Portable railways are used on a number of farms in France, and the French *Journal of Practical Agriculture* states that there is likely to be an important extension of the system. It is pointed out that by these lines crops can be moved much more rapidly than by ordinary cartage; that the power required is much less; that asses or mules can thus do work for which horses or oxen would be required, or a steam motor can be employed; and that these lines can be laid through lands over which it would be too expensive to build roads. Steel instead of iron rails are recommended. A complete plant for about 1660ft. of line, six cars, crossings, switches, &c., can, it is claimed, be built for £80 to £100. Portable railways are also exclusively used in the construction of public works and on large contracting undertakings.

A large number of gentlemen, representing the Southampton Harbour Board, the South-Western Railway Company, and the shipping interests of the port, were conveyed by special steamer to the Solent yesterday, to inspect the four new gas buoys which have been placed in the Solent, for its safe navigation at any time during the night. There are four gas buoys, one at East Lepe, one at West Brambles, one at East Brambles, and the fourth at Netley Shoal. The light can be easily distinguishable for two and a-half miles. Each buoy is charged to last six weeks. The new buoys are on the system of the Pintsch's Lighting Company and will now give a perfectly safe passage from the Needles to Southampton Docks at any state of tide or weather, and they are looked upon by mariners as the greatest improvement ever effected so far as the navigation of the Solent is concerned.

The Travnik-Bugojno of the Lasva-Arrano, a length of 25½ miles, has been completed and opened for traffic. Although the preliminary surveys, plans and estimates for the continuation of this line to the Bosnian frontier at Arrano, and thence across Dalmatia to Spalabo have been made, nothing has been definitely settled as to it. The branch line from Dolnji Vakuf to Jaïce, 21⅛ miles in length, is nearly completed, but will not be opened to public traffic before next spring. The total length of railways in Bosnia and Herzegovina is 494 miles, comprising lines of the ordinary European gauge:—Banjabuka-Doberlin, 70¼ miles; Austrian Brod-Bosnian Brod, 2¼ miles. Narrow gauge lines of 2ft. 5$\frac{9}{16}$in.:—Brod Serajevo, 166⅔ miles; Tarajevo-Metkavic, 110 miles; Lasva-Bugojno, 44¼ miles; Dabaj-Timin Han, 41½ miles; Usora Valley, 29½ miles; Dolnji Vakuf Jaïce, 21⅛ miles; Vagasca-Cerljanovic, 12¾ miles; Ilidze-Bath Ilidze, ¾ miles. The Vagasca-Cerljanovic and Usara Valley lines have been constructed by private companies for the transport of minerals and timber, and there is not any regular service of trains or passenger traffic over them. A magnificent carriage road has been completed between Banjabuka and Jaïce, so constructed that to make it a railway there is nothing required but to lay the rails.

## NOTES AND MEMORANDA.

In Brussels cabinet makers work from 14 to 18 hours per day, street car employés 17, and masons 13 hours per day.

According to a recent determination of Professor Richarz, the smallest possible quantity of electricity is such that 430 multiplied by a million cubed will give the number of atoms contained in a coulomb.

We understand that Sir Howard Grubb has made plans for a 10ft. reflector telescope, weighing nearly 100 tons, to cost about £30,000. It is proposed in mounting the mirror to float it in an enormous tank of water, 60ft. in diameter and 100ft. high, in order to eliminate the friction of motion.

Over seventy miles of hydraulic mains are laid in London, the working pressure being 750lb. per square inch, the power being available day and night. The number of machines worked from the Power Company in 1884, ten years ago, was 59; the number now is 2220.

The export of flour from the Hungarian mills through the port of Fiume during the first ten months of the current year, January 1st to October 31st, amounted to 57,614 tons. About 75 per cent. of the total was for ports in Great Britain; London, Liverpool, Glasgow, Hull, and Leith taking 42,000 tons.

According to a recent German patent, benzine can be rendered unfit for use in a lamp, while it remains equally good for use in a benzine motor, by mixing from 1½ per cent. to 3 per cent. of linseed oil varnish with it. The varnish collects in the fore chamber of the motor, while the vapour of the benzine goes on and does the work.

Cryostase is the name conferred by a German chemist—Natur—upon a newly-discovered body possessing the unusual property of being liquid at a temperature below the freezing point, and solidifying under the influence of heat—in which respect it is absolutely unique. This body may be obtained by mixing together equal parts of phenol, camphor, and saponin, to which is added a slightly smaller quantity of oil of turpentine.

In a new process for colouring leather by electrical action, the hide is stretched upon a metallic table and covered, except at the edges, with the colouring liquid. *Electricity*, of New York, says that a difference of potential is established between the liquid and the metallic table. The effect of the electric current is to cause the pores of the skin to open, whereby the colouring is enabled to penetrate deeply into its tissue.

The results of carefully-kept records of the input and output of accumulators in constant use at the Clichy sector in Paris are given in *l'Industrie Electrique*. The battery consists of two sets of 250 cells each; the total weight of plates in a cell is 330 lb., the normal output 250 ampères, and the corresponding capacity 2000 ampère-hours; the necessary increase in voltage for charging being obtained by means of a separate dynamo. A table is given containing the monthly charges and discharges in watt-hours and the efficiency for each month, the mean of which is 69 per cent.

At a recent meeting of the Sugar Planters' Association in New Orleans, a paper was read accompanied by samples of sugar demonstrating the possibility of sugar refinement by electricity. The samples sent had been treated by being boiled through a bag; boiled down in open pan; no purging, no boneblack, and no molasses left. He claimed the cost could be materially reduced. By the elimination of all nitrogenous substances from melted sugar by electricity and aluminium he was able, he said, to polarise 99 per cent. and crystallise the entire syrup. People are likely, however, to be shy of electric sugar refining.

Mr. P. L. Gray, of the Mason Science College, Birmingham, recently made experiments with a view to determine the lowest temperatures at which bodies heated could be made visible in the dark. The experiments were conducted with bright and lamp-blacked platinum strips, and gave the following results:—During the morning hours, when the eye is least sensitive to radiation of low frequency, the minimum temperature of visibility of a solid is about 470 deg. C.; at night-time this temperature is reduced to 410 deg. C., and after resting the eye for some time in complete darkness, the temperature may be still further reduced to 370 deg.

Dr. Lunge, of Zurich, the well-known authority on coal tar and ammonia, observes the viscosity of tar in a very simple manner. He uses a glass vessel like an areometer, with a cylindrical bulb below and a narrow tube above, graduated to show specific gravities. He takes a watch in one hand, and the instrument in the other, and at an exact minute he drops the latter into the tar; he then counts the exact number of seconds taken by it to fall to the 1250 mark; this observation, with the aid of tables, enables the viscosity to be readily ascertained. Care must be taken that all observations are made at the same temperature. Dr. Lunge gives an account of this instrument and its use in the *Zeitschrift fur Angewandte Chemie*, August 1st, 1894.

A new method for rapidly removing iron parts shrunk on hot, like a crank on a shaft, has been communicated by M. Raffard to the Bulletin Technologique of the French Société des Anciens Eleves des Ecoles Nationales d'Arts et Metiers. An endeavour had been made to take off the outer hoop of a Laval turbine by heating it with a gas blowpipe; but the heat was communicated too quickly throughout the whole mass to give a sufficient difference of expansion in the hoop alone, so as to loosen it, and there appeared no alternative but to cut it. In such a case, M. Raffard recommends that molten lead be run round the part to be detached—a method he applied with success in 1860 at the Soho Foundry, Melbourne, in removing a crank that had been shrunk on a shaft 8in. in diameter.

From the latest returns compiled by "Lloyd's Register of Shipping," it appears that, excluding warships, there were 327 vessels of 653,331 tons gross under construction in the United Kingdom at the close of the quarter ended September 30th, 1894. The present returns are less than those of the previous quarter by about 65,000 tons. The reduction occurs both in steam and sailing tonnage, but is much greater proportionately in the latter. In fact the returns of sailing tonnage under construction are now less than at any time since 1879. It is noticeable, moreover, that the total tonnage which has been commenced during the quarter is unusually low. The actual figures will be seen on reference to Table 3. Last quarter these figures were exceeded by 83 per cent. In particular, attention may be drawn to the fact that the sailing tonnage commenced amounted only to 2320 tons, as compared with 22,960 tons commenced last quarter, and 91,250 tons commenced in the last quarter of 1891.

According to recent reports from Washington, the United States Navy Department has just completed a test of aluminium as a material for ships' boats, with the object of determining its adaptability to naval uses. The utility on board ship of this material is much decreased by its susceptibility to the corrosive action of salt water. Accordingly, two sheets, 1-16th of an inch thick, were immersed for three months at the Norfolk Navy Yard. One was of pure metal, and the other slightly alloyed with nickel. The pure plate was thickly covered with barnacles throughout the surface, and was more or less pitted by the action of salt water. The alloyed plate was incrusted with smaller barnacles, and was badly corroded, being perforated and eaten away over much of its exposed surface. This plate was as injuriously affected as a combination of iron and copper would have been with the same exposure. The claim that barnacles would not adhere to the metal was not substantiated in the smallest degree; consequently, aluminium cannot be recommended for use in salt water.

## MISCELLANEA.

The sugar industry in India appears to be prospering. There are in course of construction three large sugar refineries—one in Bengal, another in the Bombay Presidency, and the third at Cawnpore.

The Sultan of Turkey has conferred upon Mr. Joseph Ruston the order of the Osmanié, in recognition of the merits of machinery supplied by Ruston, Proctor, and Co., to the Imperial farms and agricultural schools.

Jaffa, having become the seaboard terminus of the Jaff-Jerusalem Railway, is now contemplating the construction of a port, with a tramway to the railway station. The Turkish Minister of Public Works has the matter in hand.

Two more torpedo boat destroyers were launched last week, the Boxer and the Contest. The former, built by Messrs. J. I. Thornycroft and Co., is 200ft. long, the latter, by Messrs. Laird Bros., being 208ft. long. Both are of 19ft. beam.

We hear that Messrs. Fleming and Ferguson, Phœnix Works, Paisley, have secured an order for three of their "Clyde" water-tube boilers and set of their two-crank triple-expansion engines to indicate 500-horse power, for the New Gordon Diamond Mining Company, Kimberley.

We have received a sample of asbestos covering for water and other pipes from the Bell's Asbestos Company, which consists of asbestos cloth wound round the pipe to a considerable thickness, and kept in place by a varnished cloth cover, and held by a series of easily applied light metal hoops and fastenings.

The improvement of Colchester Harbour is to be undertaken at an early date. The *Miller* says Mr. Wheeler, M. Inst. C.E., who has been consulted by the Corporation, has drafted a comprehensive scheme for widening and deepening the river Colne. The present facilities are very inadequate, and unless something is done, trade is not unlikely to desert the port.

The Admiralty have ordered that vent sealing tubes with ball—both electric and percussion—are, when the existing stock is exhausted, to be superseded by vent sealing tubes without ball, and to be used in conjunction with cordite primers in breech-loading guns of 8in. calibre and upwards. The cordite primers are for the purpose of clearing the vent of fouling and conveying the flash from the tube to the charge, and they are to be inserted in the vent before entering the tube.

The Portuguese Government have entered into a contract with Messrs. Yarrow and Company, of Poplar, for the immediate construction of two shallow draught stern-wheel gunboats, to take part in the Portuguese operations at Lourenco Marques. The vessels are to be 89ft. in length by 18ft. beam, and will have a draught of 18in., and a speed of ten miles an hour. They will be somewhat similar to the Mosquito and Herald, built by the same firm for the British Government for service on the Zambesi.

The recent bold torpedo-boat attack upon Port Arthur was led by the Kotaka, constructed by Messrs. Yarrow and Co., in the year 1886, for the Japanese Government. She is of nearly the same dimensions as the destroyers of the Hornet class now building for the Admiralty, being 170ft. in length by 20ft. beam, propelled by twin-screws, and having a speed of nineteen knots. The distinctive feature in her design is that the machinery compartment is completely armour-plated with 1in. steel plates, so as to protect this portion of the vessel, the rest of the hull being subdivided into a very large number of small water-tight compartments. It is a remarkable fact that the Japanese Government was the first to adopt seagoing torpedo boats, and the Kotaka is probably the only armoured torpedo boat afloat.

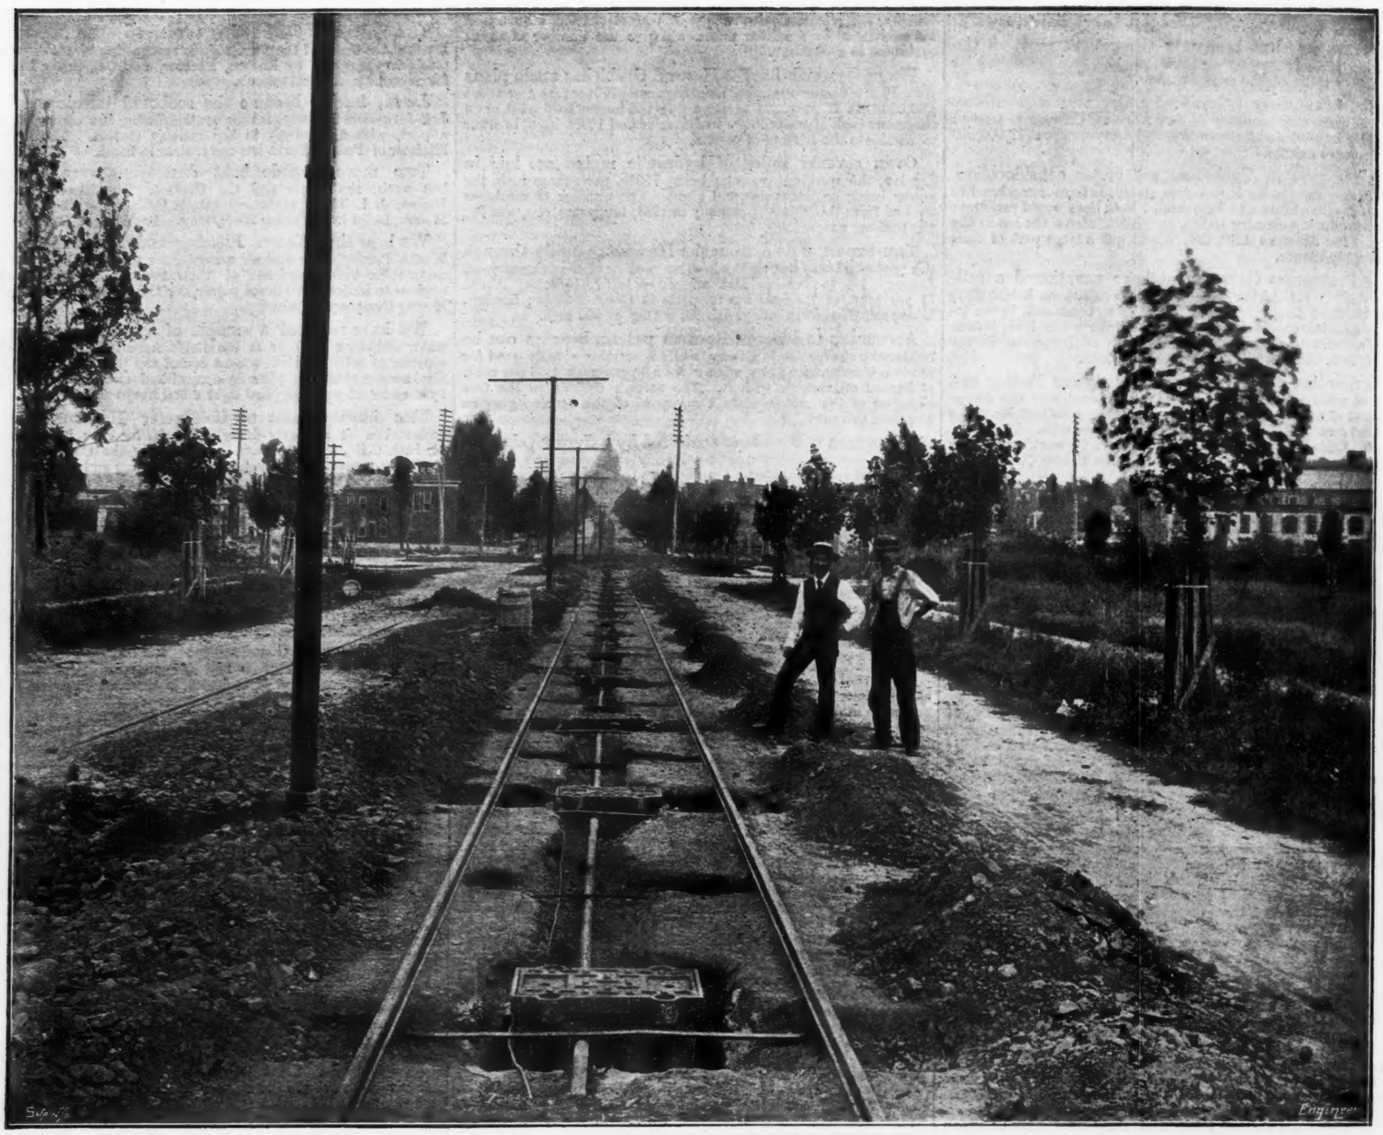
A meeting of the cement trade was held at the London Chamber of Commerce on Friday last for the purpose of receiving and adopting, or otherwise, certain recommendations of the Special Committee which has been appointed to investigate and report upon the extent of the practice of admixtures with Portland cement, and as to the justifiability thereof. The trade, with only one dissentient, adopted the recommendation of the committee, that it was advisable that all manufacturers of Portland cement, who have used any outside material or materials in the manufacture of that article, should at once discontinue the practice. The use, however, of not more than two per cent. of gypsum, as practised by the German manufacturers for the purpose of regulating the setting of the cement, is considered optional.

At the recent annual dinner of the Leeds Association of Engineers, Mr. E. Windsor Richards said he had just returned from America, and he was quite sure they could not wonder that there should be depression in trade there, because the power of production was enormous. We were a Free Trade country, but the Americans were worse off, although they were a Protected country. Ten years ago, at Messrs. Bolckow's, they rolled 4000 tons of rails per week, and that was considered a great thing; but at Messrs. Carnegie's alone they turned out 8000 tons of rails per week, and these rails were entirely manipulated by machinery. If America had only Free Trade, he was perfectly sure she would rob England of a great deal of trade. What he feared America would do was that she would have such an amount of Protection that she would sell to China at very cheap rates in the same way that continental makers did, and so they in England would be greater sufferers still.

The report to the Board of Trade upon the working of the Boiler Explosions Act during the twelve months ended June 30th last shows that 104 cases of explosion—the largest number dealt with since the Act of 1882 came into force—were inquired into within the period under review. Though the explosions were so abnormally numerous, the loss of life caused by them was below the annual average. Altogether 24 persons were killed and 54 injured. Formal inquiries were held in 23 cases—those in which were *prima facie* evidence of any neglect. In the majority of these the owners of the boilers were ordered to pay costs ranging in amount from £5 to £60. In only one case formally investigated was an explosion attributed to an unavoidable accident; in three cases only was it found that no one was to blame. Many of the explosions with regard to which preliminary inquiries were held were of a trivial nature. The report dwells upon precautions during severe frost. Boilers should be fitted with means for preventing undue pressure; in the absence of such fitting the temperature of the water in the boiler or connections should not be allowed to fal to freezing point.

On Friday last the time expired for the deposit of plans and books of reference relating to schemes which it is intended to promote in the coming session. There were deposited fifty plans of railway schemes, three tramways, and forty miscellaneous; 65 provisional orders relating principally to gas and water undertakings, and 31 relating to electric lighting; a total of 189, as compared with 196 deposited last year. Among those relating to the metropolis were the London, Walthamstow, and Epping Forest Railway, Uxbridge and Rickmansworth Railway, London, Deptford, and Greenwich Tramways, Chelsea Waterworks, Lambeth Waterworks, London County Council Tower Bridge southern approach, to which the principle of betterment is sought to be applied, the Vauxhall Bridge rebuilding, and the General Powers Bill. The eight Bills of the County Council for the acquisition of the water companies did not require to have plans deposited in respect of them, as no new works are contemplated. Other schemes were the Strand Improvement, Southend-on-Sea Corporation, Eastbourne Improvement, London, Deptford, and Greenwich Tramways, London United Tramways, Mid-Kent Water, Twickenham Local Board, and electric lighting schemes for Battersea, St. Olave, St. George, the Strand, Walthamstow, and St. Mary, Newington.

# CLOSED CONDUIT ELECTRICAL TRAMWAY, WASHINGTON, U.S.A.



## A CLOSED CONDUIT SYSTEM FOR ELECTRICAL TRAMWAYS.

An entirely new system of electrical tramcar propulsion is now successfully operating in daily service upon a branch of the Eckington and Soldiers' Home Tramway, about one mile in length, situated upon North Capitol-street, Washington, D.C., which fully complies with the three main requirements of an electric tramway, viz., minimum first cost of construction, maximum economy in working, both of power and maintenance, and absolute safety to both passengers and the general public. The car is of the ordinary description, working upon electric lines, except that in lieu of a trolly stand upon the roof, it has suspended from the under-side of its framing, as shown in Fig. 1, two iron bars, the same length as the car, hung upon light springs, and adjustable by means of screws, known as the energizing and collecting bars respectively. Beneath one of the seats of the car is a small storage battery consisting of six cells, which is arranged to discharge a low potential current at a pressure of about eight volts, and is connected by means of suitable wiring to the energizing bar.

In the centre of the line are placed, at intervals of about 15ft. apart, hermetically sealed cast iron boxes, upon the lids of which, properly insulated, are two raised surfaces, as shown in Fig. 2, known as the energizing and collecting plates respectively, corresponding with the bars suspended from the car, which slide lightly upon them. Securely attached to the underside of the lids of the cast iron boxes are a series of simple electro-magnets, as shown in Figs. 3 and 4, each wound with a fine copper wire, one end of which is connected to the energizing plate. The free poles of the magnet hang down vertically, and work in connection with an armature attached to a bridge piece, upon which are two carbon faces, directly above each of which is a corresponding carbon face fixed to the slate bed of the magnet. One of the fixed carbon faces is directly connected to the main cable, which conveys the 500-volt current from the generators at the power house—and runs in an iron pipe through all the boxes, as shown in Fig. 5 above—and the other carbon face to the collecting plate upon the box lid.

Fig. 1. SHOWING ENERGISING AND COLLECTING BARS

The operation of the car then becomes as follows:—The battery discharges its low pressure current along the energizing bar through the corresponding plate upon the box lid to the electro-magnet, which, upon becoming energized, instantly attracts the armature and bridge piece, thus bringing all four carbon faces into close contact, and completing the circuit which allows the current to flow from the main cable up through the collecting plate to its corresponding bar upon the car, whence it is admitted to the motors in the usual manner.

The above description applies only to single lines. Where there is a double line the arrangement is somewhat modified, and in the new roads now under construction upon this system another novel feature has been introduced in the shape of a metallic return, which is effected by simply adding a third or return circuit bar to the car, and connecting a third contact plate upon the street with a cable which, laid in the same trench together with the main cable, returns the current after doing its work to the generators at the power house. In double lines the construction is as follows:—The cast iron boxes, at the same distance apart as before described, are placed between the lines, or, in railway parlance, in the six-foot, and the electro-magnets working the up and down roads placed in the same box. The collecting, energizing, and return contact plates are then set in the centre of each line, in the same manner as illustrated for a single line, with the exception that they are set upon blocks of either terra-cotta or granite, as may be preferred by the local authorities, instead of on the cast iron box lid, as shown. All the connections are made in a suitably designed cast iron water-tight dish underneath the blocks, and taken to the cast iron box in the six-foot in an iron pipe. The advantages of this arrangement are manifold, not only reducing the cost of construction, but enabling the whole system to be installed with little or no interruption to the traffic on the road.

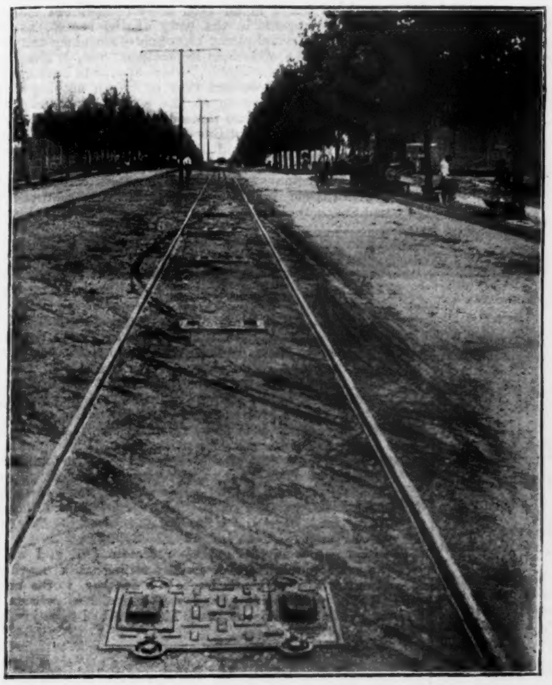

Fig. 6—STREET UNDER WORKING CONDITIONS

The American engineer correspondent, to whom we are indebted for these particulars, states that he has had ample opportunities of thoroughly examining the work, and of travelling upon the cars under all sorts of conditions, and he thinks that this system must take preference over any other electrical underground system at present on the market in his country. The difference between the length of the collecting bars and the centres of the boxes insures that good contact shall have been made with the forward plate before the rear one is left, and as proof of this, even when travelling at a considerably greater rate of speed than the city authorities allow, a steady and unflickering light is maintained in the lamps of the car, which draw their electric current from the same source as the motors. The action of the electro-magnets is instantaneous, both in picking up the current as the car approaches and of dropping it again as it leaves. To obtain current or shock from any contact plate is impossible, as should any part of the electro-magnetic switch fail, it simply leaves the plates dead, and the car has to drift by its own momentum to the next box. So simple, however, is the construction of these switches or electro-magnets, with the total absence of anything in the shape of a mechanical movement, that during the three months that the current has been on the existing road nothing in the shape of trouble has been experienced so far, which, considering that this is the first road installed upon this principle, speaks volumes. From tests applied by the Wheatstone bridge and tangent galvanometer, after flooding certain of the boxes with water with the car keeping the switches closed, the leakage was found to be less than one-half of 1 per cent. of the power required per car.

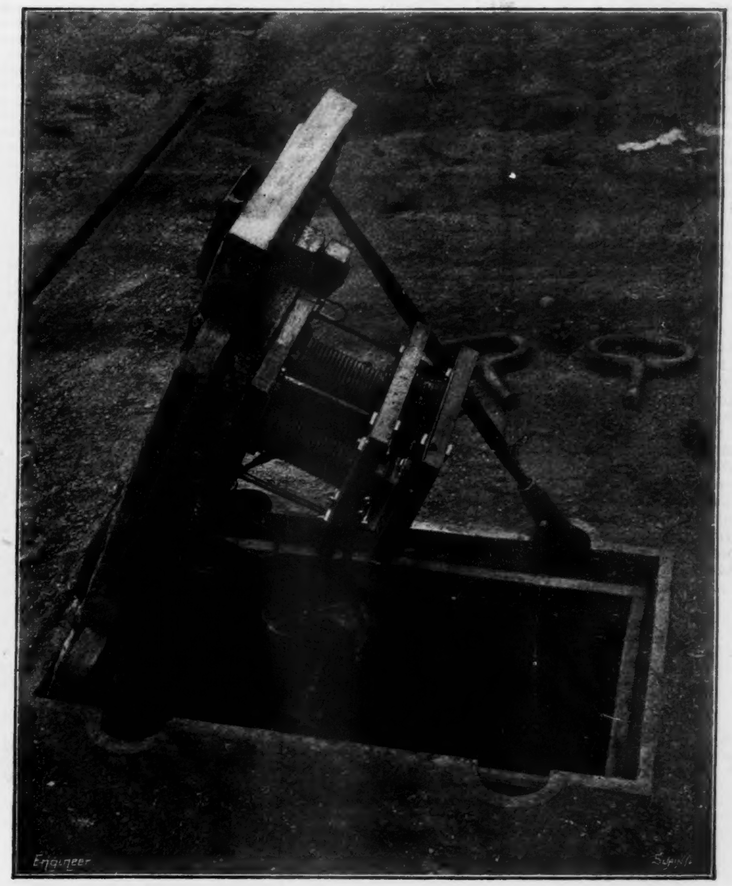

Fig. 3—MAGNET BOX OPEN

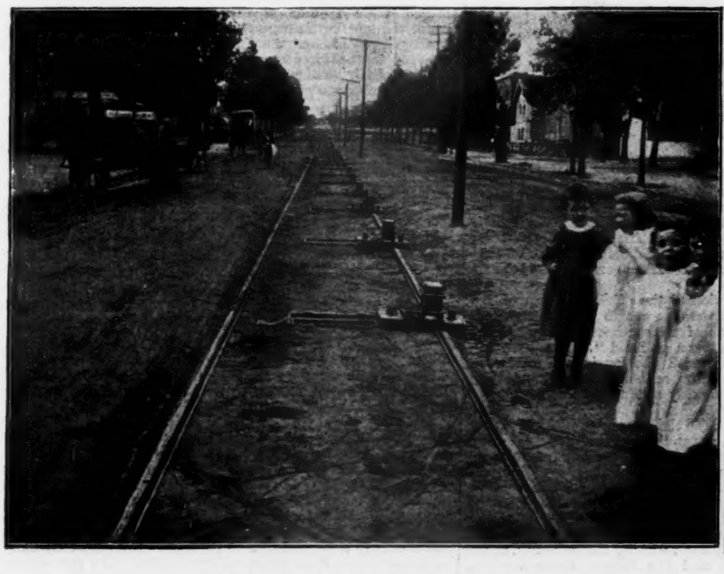

Fig. 4—MAGNET BOXES OPEN

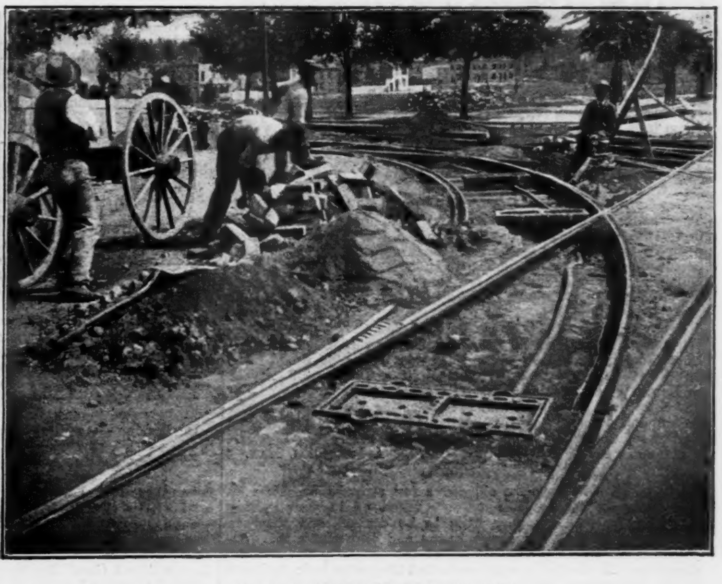

Fig. 7—ARRANGEMENT ON CURVES

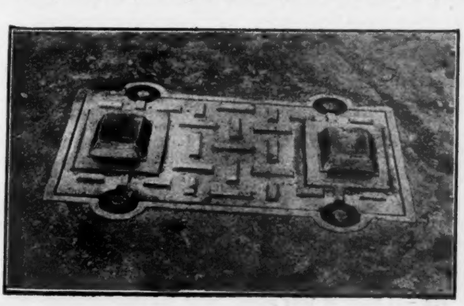

Fig. 2—MAGNET BOX

During snowstorms the lines will have to be kept clear of snow in the usual manner, and when frost after rain is expected a car will be kept in operation to keep the contact plates clear of ice. The contact plates stand only about three-quarters of an inch above the pavement and offer little or no obstruction to vehicular traffic. The cost of installing this system is, we are told by our correspondent, trifling compared with the elaborate preparations required for an open conduit, being only about £7000 per mile of double line, including the metallic return, and all the cables, feeders, and conduit for same, and the system is obviously superior for cities to any overhead line, however cheap. It is unnecessary, however, to admit that experience in the working of the system, especially in respect of the collector bars, is required.

No doubt many of our readers may wish to obtain further information concerning a system which has apparently much to recommend it. We must refer them to the Electro-Magnetic Traction Company, Corcoran-building, Washington, or to Mr. E. W. Creecy, at the same address.

## 900 I.H.P. COMPOUND FIXED ENGINE.

THE engine illustrated on p. 488 is a fine specimen of modern engineering, and has been manufactured by the well-known engine makers, Messrs. Robey and Co., Limited, of the Globe Works, Lincoln. As will be seen, the cylinders are placed side by side, with the fly-wheel in the centre, this method having many advantages. The diameter of the high-pressure cylinder is 24in., low-pressure 40in., and stroke 48in.; and with a steam pressure of 100 lb. per square inch the engine will, when condensing, give off 900 indicated horse-power. A condenser, of the injection type, worked by an extension of the low-pressure piston-rod through a rocking lever, is placed at the rear of the low-pressure cylinder, and at a lower level; the air pumps are single-acting, two in number, each 23½in. diameter. The main shaft is exceedingly massive, being 15½in. diameter in the centre, the main bearings being 12in. diameter by 24in. long, thus giving ample bearing surface.

The power is transmitted by means of a fly-wheel, 18ft. diameter, grooved for fourteen ropes, 1¾in. diameter, and the rim is built up of ten segments, the latter being carried by ten arms, which are fastened in the central boss by double cottars. The main feature, however, in this engine is the trip valve gear, which is Richardson and Rowland's patent, and works with a smoothness and precision which leaves nothing to be desired. The inlet valves on the high-pressure cylinder are of the double-beat type, and are actuated by trip levers, which again receive their motion from a cross shaft driven from the main shaft of the engine by cut gearing. The trippers which lift the valve are coupled to the governor, which by means of a simple motion adjusts the cut-off from zero to ¾, by sliding the tripper into longer or shorter communication with the tripping lever. This arrangement has been found in numerous examples to be most effective, and controls the speed of the engine within less than one per cent. on ordinary variations in load. The exhaust valves are underneath the cylinders, and have large openings with a very small movement, thus giving a free exhaust, and draining the cylinders effectually. A large receiver is situated between the two cylinders, into which the high-pressure exhausts; here it is re-heated by means of a live steam coil, and enters the low-pressure cylinder at a slightly enhanced pressure.

The economy of steam consumption in this type of engine has been proved to be very considerable, and with the engine illustrated the consumption has been brought to the lowest practicable point. As a proof of the accurate balancing of all parts, the engine was erected on a temporary foundation of timber and moulding boxes, at a height of 10ft. from the ground level, and on this slight foundation, run at the full speed of 75 revolutions per minute, with scarcely any perceptible vibration. The engine is for driving a large mill in Russia, and has been specially designed to render transport easier, the girder bed being made in two halves, and bolted securely together, and a foot placed in the centre, whereby absolute rigidity is obtained. The fly-wheel has been turned dead true, a result seldom obtained with equal accuracy with so large a wheel. We have seen the engine run at all speeds, from the lowest possible, up, as we have said, to 75 revolutions, and with greatest steadiness. Above 75 revolutions the admission valves do not open at all, as the governor was set at the time of our visit. The cylinders are lagged with blue steel, instead of the objectionable wood still retained by many makers, largely, we understand, because of the difficulty met with in obtaining in this country suitable lagging steel.

The workmanship of the engine is unusually fine. It is not an affair of polish and bright work, but of real accuracy of adjustment and lining out. Right angles *are* right angles, bearing surfaces are in contact all over, and so on. In short, the workmanship will compare most favourably with that of the best continental makers, and will maintain the reputation of English builders of stationary engines abroad.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### LOCOMOTIVES AND TRAINS.

SIR,—I—and I have no doubt many of your readers—have read with much interest and pleasure your very practical article on page 470, last week. The article, I consider, is just now of the very greatest use, as it throws much light on the long recent discussion in your columns, and gives some idea of the difficulties that a driver has always to contend with. Because there happened to be two engines upon a train when it came into collision, some of your readers seem to rave against the use of a pilot engine. What had the pilot engine to do with this collision? If there had been no pilot engine it would have been the train driver who would have been killed, not the pilot man. What do railway companies keep pilot engines for, always in steam, if they are not to be used in case of necessity?

From the tone of many of the letters on this matter which have appeared in your columns I should say the writers are amateurs, who have perhaps never travelled on the footplate of an express engine. I should like to ask these gentlemen a few plain questions. The driver of the up express was a man living at York; but the engine he had was 1622, which belongs to Newcastle, and only runs north to Edinburgh. Does not that seem strange; does it not point to the conclusion that the driver had not his usual regular engine? The writers of letters to your paper have not told us that the driver had previously had to leave his usual engine at Newcastle.

Why was 1622 so "sulky" on this occasion? Perhaps she did not approve of being sent to York, perhaps she did not like to be taken from her usual driver, perhaps the driver did not know her little "fads" and "whims." Anyhow, time was lost to Darlington, and there was only about 80 lb. of steam in the boiler. With such a low and falling pressure the air brake was always likely to give trouble by not releasing quickly.

Now, what will our amateur writers say should have been done? They blame the driver for taking a "pilot," but what was he to do? His engine had to go to York, so had he. There was every prospect that if helped over the temporary difficulty the train engine would soon be all right again and get steam. Then, as you point out in your able article, it would never have done for the driver to start with such a low pressure of air—that, in fact, he had no efficient brake power.

Let me, in short, tell your amateur readers that by taking the Darlington pilot engine the driver did just the very thing he should have done, and if he had taken any other course he would have been very properly seriously blamed, if not taken off express driving. If instead of blaming pilot engines your correspondents had considered why it was that the self-acting fog signal did not go off and warn the drivers of the express, they would have written something of very great interest to

December 3rd. A PRACTICAL MAN.

SIR,—I should like to be allowed a few remarks on this very interesting discussion. The attitude taken up in your leading articles seem to leave very little to be desired, and they are evidently written by a man who knows and appreciates the difficulties of the problem. The reason of the similarity of the Caledonian and North British engines is that they were both designed by Mr. Drummond, who was locomotive superintendent of, first, the North British, and then, until a few years back, of the Caledonian.

In all probability the fact that the characters of the rival roads between Edinburgh and Carlisle are not very dissimilar, furnishes another reason for similar designs being adhered to. The difference between, say, the Great Northern and the Midland lines is a point frequently overlooked, but it would account for much in the way of difference in design in the engines used by each company. The critics of modern express engines appear to overlook the fact that the duty of these is not simply to keep time under ordinary circumstances, but to keep it, aye, and make up time, under the most adverse conditions, if such be at all possible.

Most of your correspondents state or imply that the cause of our Scotch express trains being frequently late is due to the inefficiency of the modern express engine, and blame it accordingly. Now, in my opinion, the chief reason must be put down to another cause altogether. It is simply the fact that the stipulated stopping time is so often exceeded at—taking the West Coast as an example—important stations like Crewe, Preston, and Carlisle. Some of this may be due to making up trains, which is unavoidable. Further, I am of opinion that this delay is largely due to luggage, which is the cause of endless confusion.

The railway companies should absolutely limit each passenger on their fastest expresses to 30 lb. of luggage. Several advantages would accrue to the travelling public—which outweigh in my estimation any objections—if this system were properly carried out. Some of them are these: The express trains would keep better time, thus to some extent rendering travelling safer; no responsibility or anxiety about luggage; a great diminution in tipping. At first luggage could be sent by what are called fast trains, and an amount equivalent to 100 lb. per head carried free; over this to be paid for, and the Company allowed to make a small charge for collection and delivery. In this way the public would merely have the slight disadvantage of waiting a few hours for luggage.

Very soon the railway companies would arrange fast luggage trains, and what is now a terrific nuisance all round would cease. A further advantage would be that much less luggage would be lost, while the railway officials would find an immense saving in worry. Let anyone look at, say, Perth Station, or Waverley Station, Edinburgh, any day in August, and they will appreciate the luggage trouble. This is not, perhaps, engineering, but the subject appeals to a a much wider circle, and I strongly believe, if some system of the kind were adopted, we should hear much less of the alleged inability of modern express engines to do their work.

As a trial of the plan indicated, let the North-Western alter their 10 a.m. train from Euston and corresponding down trains into corridor luncheon expresses, allow only the very little luggage mentioned, cut their twenty minutes' stop at Preston down to five, and run into Edinburgh at 6.15 and Euston 6.30. The other companies would follow at once. R. C. DOWIE.

Manchester, December 6th.

SIR,—After all we have had rather a storm in a teacup over the engines in the Northallerton smash as it turns out, as I guessed from the photograph that it was the big one which was helping the small one, which had an injured brake pump, and could not make steam enough. I think your article sums up the whole matter very well—the main point being that if you want to haul heavy trains punctually in every kind of weather, you must have large enough engines. That these large engines save fuel, repairs, and expenses generally, has been proved to demonstration in America long ago, and is being proved here now. When Mr. D. Drummond went from the N.B.R. to the Caledonian, and replaced their old small express engine by his famous type—which is now the standard on most lines—the saving on locomotive expenses ran to five figures in several half years.

"Permanent Way's" letter on November 23rd is very interesting, and he most happily describes what is the most wonderful daily run in the world, viz , on the Caledonian, the day express from Aberdeen, running at 54·1 miles per hour, Symington to Carlisle, with well over 200 tons on, this being done with one of Mr. Drummond's famous type of engine.

Is he correct, however, when he says a W.C.J.S. dining car weighs 33½ tons, which is just the same as a M.S.J.S one, which looks much heavier? Worsdell's engines weigh 94 tons, but Greater Britains only about 80 tons. Mr. Head is surely wrong when he makes the Empire State Express cars weigh only 30 tons; they must be 50 tons, I think. As to the question of the increase of speed and weight of trains, I look upon 1888 as the date to be kept in mind as that from which speed and weight of trains and size of locomotives began to grow. The ideal locomotive for the future is one such as Mr. Drummond had in view, I think, with 8ft. coupled drivers, the drawback being the necessity for outside cylinders.

Mr. Edward J. M. Davies, in replying to my three propositions as to the brakes on the Northallerton train, clearly shows that, had this train been made up of eight-wheeled or twelve-wheeled stock, and therefore braked on every wheel, it could be stopped at sixty miles an hour in 116ft. less than if made up, as it was, of antiquated two-thirds braked six-wheelers, or in 168ft. less if the bogie wheels on the engine had been braked in addition. Comment is needless. Mr. Bowles under-estimated the weight of this train—empty—by thirteen or fourteen tons from the first. Will nothing persuade him to come forth, and tell us where his "McDonnell engine weighing 39 tons, with pick-up tender weighing 15 tons," is or was to be found? I see the word in his letter of October 19th is "Macdonnel." NORMAN MACDONALD.

SIR,—Although I do not care about taking part in any correspondence, I think it only fair to name two other lines besides the Great Northern, on which the use of pilot engines—except in the rare case of light engines getting about from one place to another—is forbidden. The lines I refer to are the London, Brighton, and South Coast, and the South Eastern, which are both noted for the heavy loads run. Although I can make a good guess, I should like to know which company Mr. W. B. Thompson means as the one which has had more experience with 19in. cylinder engines than any other in the kingdom, and shall be glad if he will name it. E. R.

London December 3rd.

### ENGLISH AND AMERICAN LOCOMOTIVES IN SOUTH AMERICA.

SIR,—In my former letter, in your issue of the 16th inst., I indicated the views I have heard expressed by experienced commercial and locomotive men as to the tone and mode of advertising the Elordi and Esteves' report on the above subject. Time did not then permit, however, of my going into details in support of that opinion. I therefore now purpose proceeding to examine the grounds for this indictment.

I have already said that, in view of the official position of the authors, a judicial treatment of the case was to have been reasonably expected. Moreover, some of the sentiments in the report itself—for example, that it was taken in hand "to enlighten the President," and "in compliance with the President's mandate"—ought to have weighed with the authors, as one would have thought, in making them scrupulously careful to hold the scale of justice evenly between the parties.

In pursuing this subject I make no claim to any special knowledge bearing on this particular case, beyond what is to be derived from a somewhat careful examination of the report, added to some study of this branch of engineering in the time available to me from other kindred avocations, and supplemented by such information as is open to anyone who has happened to be over the ground and used his eyes with ordinary intelligence, in examining and comparing the general features and details of the rolling stock used on the two lines of railway dealt with by the authors, *i.e.*, the Buenos Ayres Great Southern and the Buenos Ayres Western, which for brevity I shall hereafter call the Great Southern and the Western respectively.

I may further premise by saying that long connection with the district, coupled with an active interest in its mechanical industries, as well as in its general commercial prosperity, gives the subject a special interest to me, for I feel that anything injuriously affecting the trade of the district is a matter of concern to one and all belonging to it. In these times of commercial depression in the district, with the cotton industry apparently on the wane and, along with it, the machine shops dependent on it much reduced in output, it is of unusual concern to us, and one cannot therefore regard with indifference the publication of even a Provincial Government report, and however unknown to the world at large the accredited authors of it may be, which report—if based on any substantial foundation of fact—would justify the transference of the locomotive industry from its old centres at home to other countries and other hands, as far at all events as foreign orders are concerned. The attack, in this instance, is directed against an individual firm; but if allowed to go unchallenged and unexposed, the same tactics will not improbably be directed—on other occasions—against other makers in this country.

Without further preface, however, I will proceed to the charge. In doing so I will take, in the first place, in support of it, what I may term the organic or structural features of the report, as distinct from its technical treatment of the subject. Now, what strikes one forcibly in this connection is, that while the opening sentences are framed in guarded and impersonal terms, as though the merits of the case alone occupied the minds of the authors—the term "builders" being used in conjunction with the equally impersonal phrase, "all the rolling stock of the Southern Railway was manufactured in England"—yet later on, when the mind of the reader may be thought to have been "seized"—to use a legal phrase—of the doctrine of the authors as to the worthlessness—worse than worthlessness—of the English locomotive, the name and address of "the maker" of the said "masses of iron" are inserted, not once, but again and again in each of the paragraphs relating to the several classes of engines coming successively under Messrs. Elordi and Esteves' condemnation, and the first disguise of "impersonal treatment" then vanishes into thin air.

But the authors have have not been content, as an examination of their report reveals, with giving the names and address of the makers of the discredited English locomotives; on the contrary they further judge it consistent with the avowedly judicial nature of their task to insert in an even more conspicuous manner, if possible—for it appears in the body of the report, as well as parenthetically in several places elsewhere—the name and address of the makers of the American locomotives, viz , "The Baldwin Locomotive Works, Philadelphia," which appear to have had such a fascination for the authors that they could see nothing worse to say in criticism thereof, even at the end of their long "comparative study"—as they are pleased to term it—than to "except a few details" from the running chorus of praise with which they felt constrained to commend the Baldwin locomotives to the favourable notice of "the President."

It is this insertion of individual names in a report avowedly dealing with the general question of the fitness, or otherwise, for the Great Southern Railway of the rolling stock which the railway company had thought fit, in the interests of its shareholders, to order during a succession of years, not experimentally, but after ample experience, on the advice of its consulting engineers, and in respect of which it is impossible to see what the names of the makers had to do with the question, coupled with the mixing up in the question—as we have seen—of the name of the makers of the American locomotives used on another line altogether, which affords ample grounds, as I think your readers will perceive, for the opinion pretty generally arrived at, namely, that the matter of the report, taken in conjunction with the manner of its circulation, gave it the character, pure and simple, of a trade circular. But let me note another point which, I think, supplies an additional clue to that I have just suggested in explanation of the general drift of the report. It is to be found in the following sentences taken from one of its concluding paragraphs. I have put in italics the more significant part of the sentence. It is as follows:—

"We think that the foregoing report is sufficiently specific to enlighten the President, and to justify us in asking him to decree that *no company be allowed in future to import in this country their locomotives without first presenting and submitting their plans to the approbation of this department.*"

In connection with this notable recommendation, I will quote just two extracts relative to American rolling stock, leaving these several extracts in their relation to one another, to the unbiassed reflection of your readers, and will henceforth pass on to the technical parts of the document. The extracts I have just alluded to are the following:—

"The American locomotives owned by the Western Railway, which were acquired, when this road was the property of the State, by the engineers, Messrs. M. Tedin and L. Rapelli, are ten for rapid trains, eight for freight trains, and twelve for switching, and were built at the Baldwin Locomotive Works, of Philadelphia, in 1889. The same works built in 1884 thirty locomotives for mixed trains, for the railway of this province."

"The construction of these sixty locomotives, notwithstanding its simplicity, is first-class, except in a few small details, which by no means affect their good conditions for service. The thirty locomotives for mixed trains have withstood very severe tests during the period when the railway had not the number necessary for its service, as, notwithstanding the excessive amount of work imposed upon them, the results have been very satisfactory and economical."

In contrast with this laudatory language, I place the following:—"It may be concluded from all the data furnished in this report that the Southern Railway locomotives are but *iron masses*, entirely injurious to the roads and interests of the company."

With the increase of salaries which would doubtless accrue to the officials of the department, whoever they might be, in consideration of the new duties suggested to be assigned to them, I have nothing directly to do. But in view of the preconceived opinion conveyed in the foregoing significant sentences, what chance, it may be asked, would the poor, discredited English locomotive have in running the gauntlet of "this department" in the Province of Argentine?

The question whether "all the data furnished in this report" does, or does not, justify the damnatory conclusions arrived at by Messrs. Elordi and Esteves regarding English locomotives, is the next branch of the subject calling for treatment; but as it will occupy more space than would be reasonable to enroach on in a single issue, I must reserve it for another occasion, supposing, in view of what I have given above, it may not seem to your readers as a mere "killing of the slain," and therefore, in your opinion, a needless enroachment on your space. VERITAS,

Manchester, November 27th.

### SIMPLEX GAS ENGINES AND THE PANTIN FLOUR MILLS.

SIR,—In these days of progress your description of what is being done in France is exceedingly interesting, as it again points to the inevitable in the near future—a revolution of the power-producing industry, or, in other words, the more direct conversion of power from heat without the intervention of a fluid and the consequent loss of latent heat.

Taking a general view of your description of the 320 indicated horse-power engine and producer plant at the Pantin Flour Mills, it appears that there is yet a wide field for inventors, and vast improvements are yet capable. If I correctly understand the engine. it is of the Otto cycle, *i.e.*, a possible impulse every second revolution; the products of combustion are only partially expelled, and the shocks are in large engines abnormally heavy; the relative values of the indicated horse-power and the brake horse-power are low; the strength of the engine framing, &c., have to be proportionate to excessive violent strains. The gas apparatus is not all that can be desired, as it is only equal to the conversion of certain classes of fuel into gas, and those classes do not adapt themselves to the requirements of this country, where the coal is of a rich bituminous nature.

What is wanted here is a producer that will deal with the small but rich bituminous coal of the North of England, worth about 5s. to 10s. per ton, and an engine approaching far more nearly to the steam engine than the Otto type of gas engine described.

Appreciating, as I do, the strides being made in France in this industry, and which should stimulate Englishmen to emulate, I must say that in my opinion there is a wide field before engineers, and I shall be much surprised if, in a short time, a far more simple and efficient construction of engine is not brought out, and a gas-working apparatus which will convert our refuse bituminous-coal into useful gas. The prospect is a large one—three-quarters of a pound of coal per actual horse-power per hour against an average of three or four pounds, or even more in the ordinary commercial steam engine.

I trust that your excellent notice will be the means of waking up Englishmen to the fact that the steam engine is virtually doomed, and that they will not be behind other nations in the production of its successor. PROGRESS.

December 5th.

### TRACTION ENGINES.

SIR,—In reply to your leader under the above heading—which appears to me to be a true version, and a correct summing up of the question at issue—I beg to offer the following suggestions for discussion, as something that might be utilised as a guide in framing new regulations for the use of steam on highways.

Every traction engine to have a licence. The municipal authorities for boroughs, and the district council board for rural districts, to be the bodies appointed to issue such licences, but to have no power to make special bye-laws for their own districts. The hackney carriage example might be followed, that is, upon certain appointed days, all the engines in a town or district would have to appear before a committee for inspection, in order to ascertain if they were in a fit state of repair, &c., to work upon the highways, and fulfilled the conditions required by Act of Parliament. This would be a good thing for many owners, as it would compel them to have a fettle up once a year, instead of allowing their engines to knock to pieces as at present.

Licences to be divided into several classes. (1) Say £2 per annum for purely agricultural engines, this to qualify them for pulling their own threshing, ploughing, sawing, and other tackle about, and allow the engines to be used for hauling farm produce and manures—for hire—for six months in the year, say from beginning of March to end of August, this would find them employment during the summer, when there is little or no threshing, and encourage hauling when parish roads were in the best condition to stand it. Engines in this class not to exceed ten tons in weight, in working order, excepting existing ploughing engines. Road rollers used for hauling road metal in summer to come in this class. Class 2—say £5—for road locomotives or hauling engines, not exceeding ten tons in weight in working order. Class 3—say £10—for similar engines between ten and twelve tons weight, and £2 a ton extra for every ton above 12 tons.

When a second-hand engine is sold the licence should go with it and qualify it until the next licensing day of the district into which it is going. A provisional licence to be obtained at any time for a new engine—without inspection—which will qualify it until the next licensing day. Makers to be allowed to deliver engines and bring them to their works without a licence. The licensing committees to have power to decide the maximum speed an engine is to run at, and whether it is necessary to have a flagman or person walking in front. Any of the above licences to qualify an engine for running upon any highway in the country.

Agricultural engines paying the £2 licence, maximum speed four miles per hour. Road locomotives over ten tons in weight—working order—and the existing noisy objectionable engines that we have heard so much about lately—no matter what their weight—maximum speed four miles per hour.

Modern high-class engines, not over ten tons in weight—working order—mounted upon springs, provided with a powerful brake acting upon both main road wheels, with a sensitive and trustworthy steering gear, all working parts to be properly cased in, and making only a minimum amount of noise, and in charge of thoroughly experienced men, to be allowed to run at a speed of six miles per hour in daylight upon country roads, but must reduce to four miles per hour through town and village streets. Wagons for these engines to be on springs. For this latter class of engine no flagman or person walking in front to be required. But upon any driver of a vehicle or person on horseback holding up the hand, the engine must be stopped, and the steersman get down and lead the animal past. Agricultural engines—£2 class—if fulfilling the required conditions, may do without a flagman. Engines which make a noise, &c., and have not working parts cased in, and are not up to modern requirements, to have a man walking in front as at present. A flagman's occupation is most dangerous, and it is quite a common form of accident for one to be run over and killed—he gets so accustomed to the rattle of the engine behind that it is upon him before he is aware of it.

Drivers of engines over the £2 licence must take out a licence (say, 2s. 6d.) showing that he is a qualified man and of good character. Steersmen of engines running at six miles per hour might have a similar licence. For certain breaches of the Act of Parliament the driver to be fined as well as the owner, and in some cases instead. This would ensure them being more careful. If any restrictions are to be made in working hours—which I think unnecessary—it should be uniform throughout the country. The time when a traction engine is most objectionable is upon a country road on a dark night, when our old "ram-shackle" friend, which you so graphically describe, is not a lovely thing to meet, especially if you are driving a horse with any metal in him at all, and you cannot see the stone heaps and gutters on the roadside. Although it is against progress to prohibit, it is not unreasonable to discourage engines running about after dark up to midnight; therefore, one doing so should have four men with it—one a considerable distance in front with a good light, and another one behind the engine, both to be provided with a whistle, and stop the engine upon the approach of a trap, &c. Both men to assist in leading the animal past. Engine, of course, to carry good lights, and proceed only at a slow speed.

All main and turnpike roads and bridges to be "up to traction engine weight," which shall be considered ordinary traffic—except in case of excessive weight, such as a very large boiler—and no owner be liable for any damage done to the surface of such road or drains or bridges, providing he is within the Act of Parliament. He should of course be liable for breaking curbstones, knocking down walls, posts, &c. Parish and bye roads can hardly be expected to come up to this standard. New engines between eight and ten tons—working order—to have main road wheels not under 16in. in width. Engines between ten and fourteen tons to have wheels 18in. wide. Wagons to have 1in. width in wheel for every ton gross loads, except large boiler wagons, &c. Until something better is introduced, I am afraid we shall have to stick to the cross strip for ordinary work, but believe that with lighter loads and increased speeds, some useful work is possible with a smooth shod wheel; this should be encouraged, as it would roll the roads. A wheel with wood blocks or shoes has been introduced, it is useful for very heavy loads upon paved streets in towns, but is much too heavy for ordinary work on macadamised roads. You invite discussion upon "what is the least offensive form that a common road locomotive available for heavy haulage can take?"

The best engine is undoubtedly one neat and compact in design, and which pulls a good load at a fair speed with little damage to the roads. Its working parts should be few in number, and properly cased in, should work without noise, and be most economical in consumption of fuel and water. I should therefore recommend a single crank compound engine about 10 tons weight, upon 18in. wheels, geared in the fast speed up to six miles per hour. The gear wheels should be few in number, and great care taken that the teeth are of the proper shape and carefully pitched, in order to run quietly. The sliding pinions should be cast together and work between bearings, and slide along a square-shaped on the shaft, instead of along feather keys, which are constantly getting loose and cause a considerable amount of clatter. The engine should be mounted upon a simple arrangement of springs, and all castings requiring strength should be made of steel in order to keep down weight. It should have a sensitive rack steerage instead of chains, which are liable to break, and might cause a serious accident at top speed. The steerage to be on the left side, so that the steersman can run close to the causeway in going through towns, &c. A powerful screw brake should be provided acting upon both main road wheels. Proper places should be made for securely holding all loose things, such as spuds, firing tools, spanners, oil cans, kettle, &c., they being responsible for a lot of clatter; the spud box on the front axle, which has recently become so fashionable, being a great producer of unnecessary sound. The above engine would be better adapted for ordinary every-day traction work than for shifting successive weights, such as large boilers.

Leeds, December 5th. J. H. M.

---

Sir,—Your article and the correspondence on traction engines is doubtless very opportune, as some steps should be taken to ameliorate the laws relating to them when working on common roads, as I am of opinion that with less restrictions they would materially assist depressed agriculture, and at the same time be the indirect means of producing better country roads. As to the wear and tear of the roads, it must be remembered that this traffic is not extraneous; it must pass over the roads, but probably in smaller units of weight. Then the question, viz., given the same weight drawn by horses, would they not do more damage My experience is they will. But another condition presents itself. Given a road with the crust probably quite sufficient to withstand the ordinary horse units of weight, say, two tons on each pair of wheels passing over it, but it breaks up under a ten-ton engine and four tons on each pair of wagon wheels, although of extra width. Can this road be considered in proper order? The local surveyor says yes; but if we give the question further consideration it may not be so plain. The whole matter becomes a financial question. A road well metalled, shaped, and drained, will improve with the use of an engine with properly designed wheels running over it, as the new metal is consolidated, and the increased expenditure for material becomes a paying investment, inasmuch as the road has a much longer proportional life. To emphasise this view, several County Councils have now their own road rollers, vans, and water-carts to accomplish this; and as mentioned by your correspondent, "J. E. S.," the roads of Kent are the best in England, and there are more engines in use on them than any other county, at the same time there is more money laid out on their consolidation.

Mr. Phillips' views as to licences—which should be charged as a registration only—inspection, damage to roads, are to the point; but what is to be the basis of the distinction between a good and bad engine? The following points suggest themselves, namely:—No engine for common haulage to exceed 12 tons in weight when fully loaded, the wheel base in diameter and contact with the road to be fixed at a given deflection. The thickness of the cross bars also to be stated, together with the total width of engine. A spring engine to minimise the force of impact is no doubt desirable both for the benefit of the roads as well as the owner, but hitherto they have not been all that has been desired; wood blocked wheels have also been tried. As to general design, to alter the general form of the present best types would doubtless be difficult, as the locomotive type of boiler is the fundamental shape to build on; but special attention is required to abate the noise from the exhaust, having due regard to the amount of induced draught required to maintain the steam boiler pressure.

Compound traction engines with two cranks do not find favour with users or drivers, single crank engines being much preferred, and the ratio of expansion being so often altered according to the requirements of the engine to the inequalities of the roads, the theoretical value of compounding disappears at once. Engines with their working gear underneath have been tried also, but a stop on a dead centre will sometimes occur at starting, hence disfavour. A large diameter of single cylinder driven well linked up, giving a good range of expansion, cheaper in first cost, with fewer working parts, is what experience has taught me to be the better engine. At the same time higher boiler pressure and piston valves are also desirable.

As to drivers, it is one of the most important considerations how to teach them. A good driver is an exceptional individual. A man may be a good mechanic and know how to handle a fixed engine well, but fails when on the foot-plate of a traction engine. I have known first-class locomotive men precisely the same. A good nerve, reliance on his engine to answer his hand, are essential. He must see no fear. Directly he sets his engine in motion he has to look where he is going, and a good driver when in difficult travelling prefers to steer himself. Having had personal experience on locomotive foot-plates also, I can safely say that a traction engine driver to cope with all emergencies, such as getting out of holes at side of roads, loading and hauling timber from woods, frosted roads, keeping down sparking, &c., must be almost born to it, and his examiner must also be of the same type.

Broad-street House, November 27th. T. E. Gakee.

---

Sir,—As one who is interested in traction engines, I am pleased to see that there is to be an effort made to remove some of the restrictions which at present press so heavily on the makers and users of these valuable machines. As an employé in a firm where large numbers of high-class traction engines are turned out annually, I consider it to be the duty of everyone who gets his crust, directly or indirectly, by the manufacture or use of these engines, to put his shoulder to the wheel and use his best endeavours to remove the absurd laws which prevent the extension of this important industry. Workmen as well as masters should therefore sink their political difference, and combine to bring some pressure on the gentlemen who represent them in Parliament, and who are, therefore, to some extent responsible for the existence of a law which should be abolished without delay.

The workmen especially should approach their members of Parliament with a view of removing some, if not all the unreasonable statutes which hamper their production, for should they succeed, they would also benefit a large number of their fellow workmen who are engaged in other industries and manufactures, seeing that cheap carriage of material and produce is so essential to good trade. I am sure the men will do their share if the matter be carefully brought to their notice. At present I consider that comparatively few of those interested know anything of the subject. I therefore beg to suggest that the leaders of the movement should by printed circular, or other means, do their best to lay the matter before their employers and all others who may be likely to help the cause.

Having had my say regarding the law relating to traction engines, I will be glad if you will grant me the space to say a word or two *re* the engines in question. After over twenty years' practical experience with traction engines of various types, working under various conditions, and having some knowledge of what is being done abroad in the way of steam hauling on common roads, I have come to the conclusion that at the present time the best traction engines in the world are made in this country, engines which leave little to be desired where heavy loads require to be moved over common roads at slow speeds, at the same time leaving the engine available for use as a stationary engine when not in use as a locomotive.

In the meantime, when the law is altered, as it should be, to allow of speeds of eight, ten, and twelve miles per hour for road locomotives, the traction engine makers of this country will rise to the occasion, and introduce engines far different in design to the present heavy, slow engines. And while I admit that the present gear-driven engines will hold their own for slow traffic, I venture to predict that the modern high-speed road locomotive of the near future will be chain-driven, mounted on laminated springs, and fitted with sufficient brake power for any and all emergencies. With regard to your suggestion as to placing the motion beneath the boiler in traction engines, I am inclined to think that so long as the present type of boiler remains in use, so long will the motion be mounted in its present position. Should, however, the water-tube boiler come into general use—a not unlikely thing—it may be found convenient to place the motion in the position suggested.

Much has been said and written regarding certificates of efficiency, &c., of the men employed to take charge of traction engines. I think the case might be met by compelling every man when in charge of an engine on the public highway to wear a numbered badge, such badge to be registered, and the holder to be liable to lose his badge for wilful neglect on his part. Of course some recommendation would be necessary to obtain such badge.

Leeds, December 3rd. Pitch Chain.

---

Sir,—In following the discussion that is at present being carried on in your valuable columns, I think that "W. C. W. T." is right in saying that it is the men in charge of the engine that are objectionable. Nine out of ten traction engine drivers are an ignorant, uncouth, dirty set of men, and have the machine under their charge in a filthy state, motion covered with oil and coke dust, and as "W. C. W. T." said, they know there is a hole one end to put coke in and a hole the other end for smoke to come out. But I think it would be a puzzle for some of these so-called drivers to tell how the smoke got to the other end, and if spoken to on any subject a grunt is the answer. With regard to your article on page 449, November 23rd issue, where you recommend undertype motion, I think it would be a detriment to a great many owners who use their traction engine for stationary work, such as travelling showmen that have their engine to haul the caravans, and when their plant is pitched, to drive a dynamo; also farmers who use the engine for threshing and steam ploughing, although I think the side frames to hide the motion would be a very great improvement. F. J. M.

December 4th.

---

Sir,—Enclosed I beg to hand you a cutting from the *Devizes and Wiltshire Gazette*, which I think will prove interesting to some of your correspondents on "Traction Engines":—

> "On Wednesday morning, the steam roller belonging to Mr. Tilke, of Melksham, which is engaged in road work by the Rural Sanitary Authority, was crossing the bridge over the brook near to Black Dog station when the bridge gave way, and the roller sank into the brook. The driver fortunately realised his dangerous position, and escaped by jumping off the engine. It is supposed that the accident is due to the recent heavy floods having undermined the bridge. Fortunately only one portion of the structure has given way, and by the aid of substantial planks light vehicles are still able to pass over in safety, although heavy traffic is stopped. The engine lies embedded in the brook with roller upwards, and there will be considerable difficulty in extricating it from its present position. Large numbers of people went out on Wednesday from Calne to see it."

The bridge is on the London—Bath main road, and is guarded by the "usual" notices. It is a stone bridge, but seems to be too small for the volume of water. The engine was one of Robey's, and weighs 13 tons. Its position might be described as lying at an angle of 45 deg., with roller on the road and fire-box in the brook. It was hauled out on Friday afternoon by means of a traction engine—such as "W. C. W. T." described in last week's number—and three shear legs. I should like to know whether such accidents are common. R. J. H. B.

December 4th.

## LABOUR AND LUXURIES.

Sir,—The letter of your correspondent, "J. C. S.," no doubt raises a very interesting question, but it has nothing whatever to do with me or any statement I have made. A sovereign is spent on an air gun, and it will do as much good so spent, I say, as if it was spent on cartridges, or buttons, or moral treatises. That is to say, it will enable the maker of air guns to procure in exchange for it food and raiment, or it may be beer, or a concertina, or shoes for his children. But the sovereign has nothing whatever to do with the air gun. The misuse of that is a point of ethics about which the sovereign knows nothing. It is really curious, and not at all uninteresting to read the various letters which have been written on this subject; not one of your correspondents has advanced a single argument or stated a single fact which controverts the proposition I have advanced. The utmost they can say is that I have overlooked the ethical part of the question. But that is precisely my intention. I hold, with Lord Farrar, that economics are one thing, ethics another.

As regards the "time element" a strange misconception seems to exist. What I have meant to convey is simply that, no matter how gold is spent, in the long run the result will be the same in the community at large. But I freely admit that as regards the individual, it may be a matter of great importance to him on what the sovereign is spent, while it is of no consequence to the individual who receives it. For example, a shoemaker needs leather in his week's work. He spends a sovereign on beer instead of on leather. In doing this he is directly benefitting the publican, and through him the brewer, the hop merchant, and the barley grower. If he had spent it on leather he would have benefitted the men of Bermondsey, and he would also have benefitted himself, his wife, and his children in the long run. The economic work of the sovereign has been performed equally well in either case; and the sovereign, it may be shown, will ultimately return to the shoe maker. But for the time being he is worse off by spending the money on beer than on leather. That is what I mean by the time element. But your readers will not fail to see that after all this is dragging in the ethical element, and the sovereign must not be held to have done its work any less satisfactorily as regards the community in one case than the other. The mistake made by your readers is that they are always dealing with men while they should think only of gold. No matter how the sovereign is spent it must be spent at the expense of one section or another of the community. Y. X.

December 3rd, 1894.

---

Sir,—If "Y. X." had previously condescended to quotation, we might have got on better. Being wholly agreed as to Lord Farrar's excellent statements, let us apply them to our case. "Ethics is a science of art and duty teaching men what they ought to do." Therefore, if a labourer says he ought not to be discharged he is talking ethics, and his fallacy, if any, is not economic. "Economic science treats of the manner in which wealth is produced and distributed." Why, then, does "Y. X." say that in political economy it matters nothing how gold—which I suppose he allows is part of wealth—is got or expended? "It is within the province of political economy to say that weak and lazy people are likely to starve, but to add, serve them right, is a question for ethics." Similarly, I was talking strict economics when I said that robbery and murder tend to diminish wealth, but the moral state of the criminal which "Y. X." discusses is a question of ethics. Two familiar aphorisms well illustrate the last passage of the quotation. The first ethical, "an honest man is the noblest work of God." The second strictly economic, "honesty is the best policy." But surely "Y. X." has been driving at something very different from the mere distinction—distinction, mind, not opposition, between ethics and economics. It is my turn to quote, and does not this more or less describe his view? "They seemed to have persuaded themselves that the most important thing for our nation was that not one sou should ever leave France; that so long as this was so, the kind and the amount of taxation, the rate of wages, the greater or less perfection of industrial arts, were things of complete indifference, provided always that one Frenchman gained what another Frenchman lost." The writer is Mollier, financier to the first Napoleon, and he is acknowledging his debt to Adam Smith whose writings had delivered him from the foolishness of his predecessors, which he thus describes. W. A. S. B.

London, December 1st.

## SHEEP SHEARING MACHINE.

Sir,—Will you allow me to point out that in your very lucid description of my sheep shearing machine, you have made a small error in attributing to me the original patent for swinging bevel gears? Such gears were made and used many years ago. My claim is only for the combination of them with swivelling sockets, so arranged as to allow a universal movement. John M. Newall.

London, December 4th.

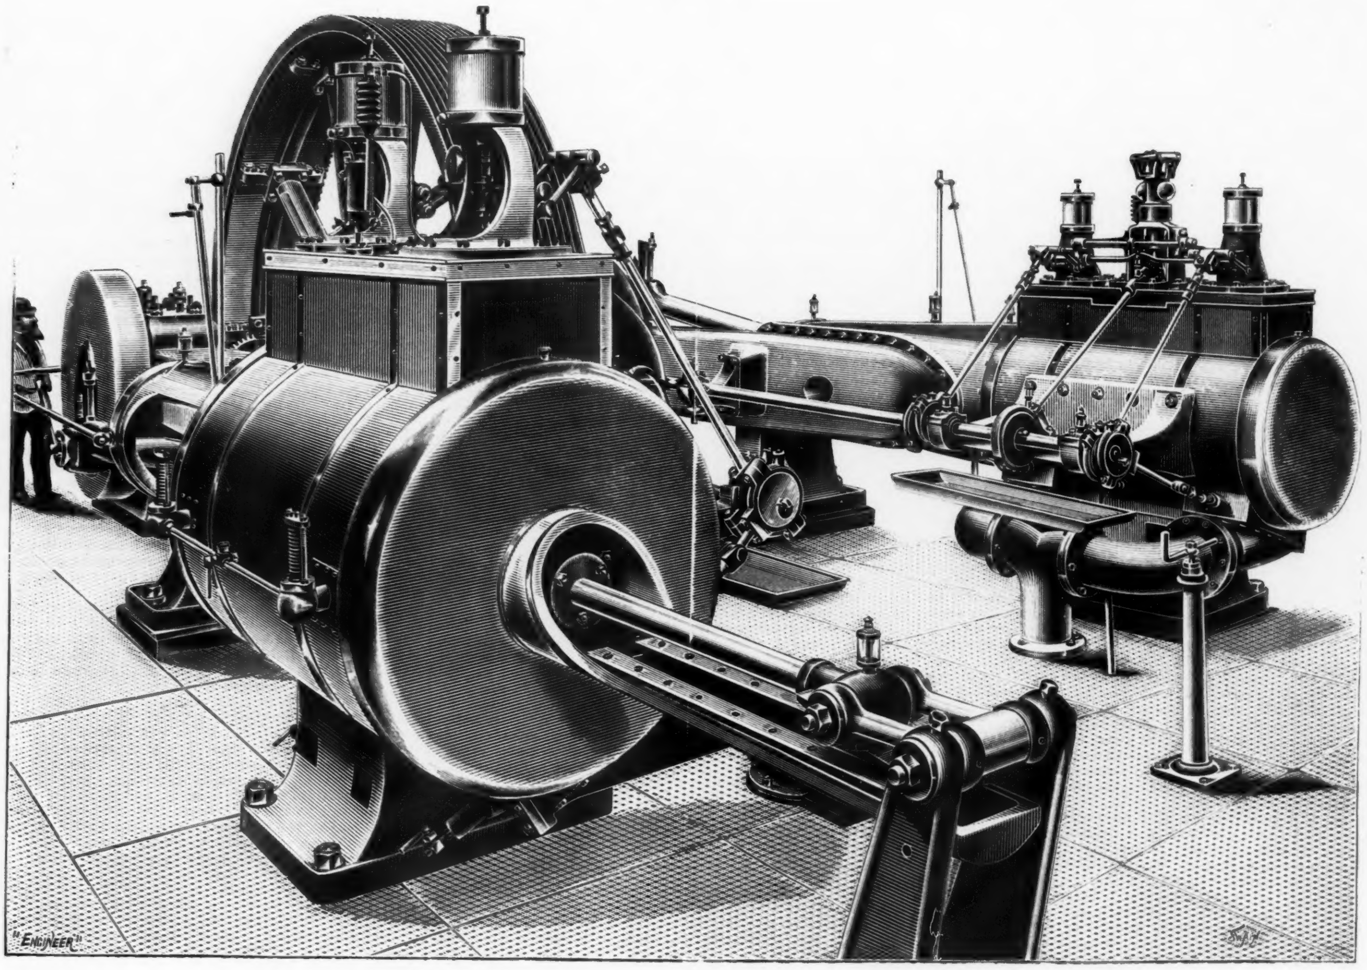
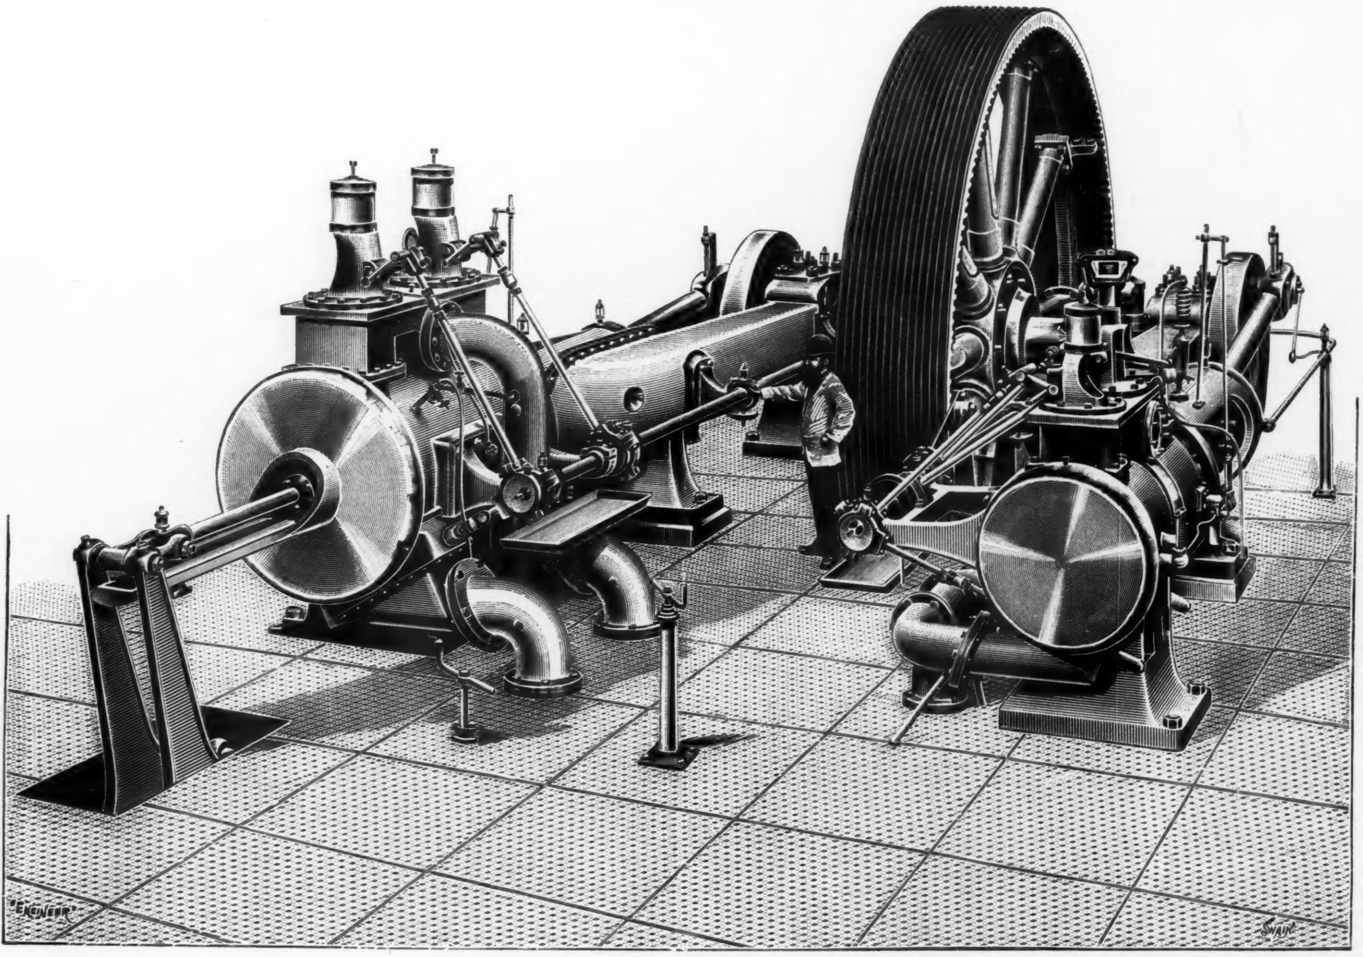
The Electric Lighting Companies and Transformer Chambers.—An inquiry is to be held at the Board of Trade on the 13th inst. into the subject of transformer chambers. The London County Council and other local authorities in the metropolis have objected to the chambers being placed in the public streets, contending that they are a serious obstruction in the roadway and may possibly interfere with the laying of gas, water, and other pipes in the future; and further, that they are a grave public danger. They have therefore urged the Board of Trade to compel electric lighting companies to place their transformer chambers on private property. On the other hand, those connected with the electric lighting industry contend that there is no danger to the public in placing the chambers in the streets, and that they can be so constructed as not to form any serious obstacle to the future use of the streets for other necessary purposes.

# NINE HUNDRED HORSE-POWER COMPOUND ENGINE

MESSRS. ROBEY AND CO., LINCOLN, ENGINEERS

(*For description see page* 85)





"ENGINEER"
SWAIN

## FOREIGN AGENTS FOR THE SALE OF THE ENGINEER

PARIS.—Boyveau and Chevillet, *Rue de la Banque.*
BERLIN.—Asher and Co., 5, *Unter den Linden.*
VIENNA.—Gerold and Co., *Booksellers.*
LEIPSIC.—A. Twietmeyer, *Bookseller.*
NEW YORK.—International News Company, 83 *and* 85, *Duane-street.*

## PUBLISHER'S NOTICE.

*The Publisher of* The Engineer *begs leave to announce that on next Friday, December* 14*th, will be published a* Special Number *of* The Engineer.

*This number will possess many features of unusual interest.*

*With it will be published* Two Supplements: *one a* Four-page Engraving *of a* Six-coupled Bogie Goods Engine *on the Highland Railway, the* Most Powerful Locomotive Engine *in Great Britain; the second a* Tracing *to the scale of three-quarters of an inch to the foot, giving a section and plan of this Engine.*

*A profusely-illustrated description of* Messrs. Sharp, Stewart, and Co.'s Locomotive Building Works, Glasgow, *with its tools and machinery, will also be found in the same issue.*

*A* Complete Set of Engravings *from photographs of the* Armoured Cruiser "Blanco Encalada," *will supply information of a kind which has never before been published.*

*Yet another feature of interest will be a* Set of Drawings *made by our special artist in the* Engine-room *of the new* Peninsular and Oriental Steamship "Caledonia."

The Engineer *for December* 14*th will also contain numerous articles on important and interesting topics.*

*This Special Number will take the place of the ordinary issue of December* 14*th, and to prevent disappointment, advertisements should reach the Office not later than Tuesday morning next, December* 11*th.*

*The price of the Number will be* 6d., *as usual (post free,* 6½d., *to any part of the United Kingdom).*

*Foreign Edition (on thin paper)* 11d. *post free to any destination outside the United Kingdom.*

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

A. J. C.—*We can only advise you to consult the numerous books on the subjects concerned in water supply in the library of the Institution of Civil Engineers.*

Permanent Way.—*Your letter is full of errors. You are quite mistaken as to the action of locomotive superintendents, as to their knowledge, and as to their work*

J. R. H. (Newcastle-on-Tyne)—*Probably the course you mention would constitute an infringement. Everything depends on the construction of the specification and its claims. A reply will be sent you by post.*

H. V. (Birmingham).—"*Le Genie Civile.*" *Paris*: 6, *Rue de la Chaussée d'Antin.* "*Les Annales Industrielles*" *Paris*: 52, *Rue Lafayette. You will find names of books by reference to the librarian in the Birmingham Library.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price* 2s. 6d. *each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, December 11th, at 8 p.m. Paper: "Colliery Surface Works," by Mr. Edw. B. Wain, Assoc. M. Inst. C.E. Friday, December 14th, at 8 p.m. Paper: "Some Experiments on the Heat Losses to the Cylinder Walls of a Steam Engine," by Mr. S. Henry Barraclough, B.E., Stud. Inst. C.E., and Mr. Lionel S. Marks, B.Sc. Mr. Bryan Donkin, M. Inst. C.E., will take the chair.

The Institution of Electrical Engineers.—Thursday, December 13th, at 7 p.m. Council meeting. Annual general meeting at 8 p.m. Annual report of the Council and election of Council and officers for the year 1895. Papers: Electrical Steep Grade Traction in Europe," by C. S. du Riche Preller, M.A., Ph.D., member; "Notes on Electric Tramways in the United States and Canada," by H. D. Wilkinson, member; "Electric Traction, with special reference to the Installation of Elevated Conductors," by R. W. Blackwell, foreign member, and Philip Dawson, associate.

Institute of Marine Engineers.—Monday, December 10th, at 8 p.m. Paper: "Wrecks and Salvage Operations," by Mr. T. W. Wailes, member.

The Sanitary Institute.—Wednesday, December 12th, at 8 p.m. Paper: "The Sanitary Aspects of the London Building Act, 1894," by George Blundell Longstaff, M.A., M.D., Oxon., F.R.C.P.

Society of Arts.—Monday, December 10th, at 8 p.m. Cantor Lectures: "Modern Developments in Explosives," by Prof. Vivian B. Lewes. Wednesday, December 12th, at 8 p.m. Paper: "Manufacture of Salt," by Thomas Ward.

## DEATH.

On the 4th inst. at Stanhope House, Park-road, Wandsworth, William Joseph Brown, aged 59 years, managing director and secretary of James Simpson and Company, engineers, London, with whom he has been associated over forty years.

# THE ENGINEER.

*DECEMBER* 7, 1894.

## LEGISLATION ON THE LONDON WATER QUESTION.

The great scheme by which the London County Council are to bring into the metropolis a new supply of water, from Wales or elsewhere, is not yet matured, and the project stands over until after the next session. But in the meantime the Council are to bring eight Bills into Parliament, comprehending the purchase of the eight metropolitan water companies. The transaction is called a "transfer," to be effected by means of an agreement, or, failing that, by the process of arbitration. As the only agreement tolerated by the County Council must be expected to correspond very closely to the terms laid down for the arbitration, it is not in any degree likely that the Companies, or any one of them, will come to an understanding with the Council on the subject. The conditions under which the arbitration is to take place are of such a nature that it is difficult to see how they can possibly receive the approval of Parliament, much less the consent of the Companies. The arbitrators are to be appointed by the Council, the Company, and the Board of Trade respectively, and this may be fair enough, but in arriving at what is called the value of the several undertakings, the arbitrators are to have regard to a variety of matters, some of a very contingent and speculative character, but all of such a nature as to reduce the amount to be paid for the acquisition of the property. Deductions are to be carried out right and left, and it is specified that "no allowance" shall be made in respect of any assumed future increase of the rateable value of buildings in the district of each company, other than an increase due to alterations or additions involving increased supply of water. Nor is any allowance to be made in respect of any past increase in rateable value, except for a similar reason. The conditions to be imposed on the arbitrators are many and various, and though some may be just, the aggregate presents so formidable an appearance that the water companies are certain to offer the most determined opposition to the passage of the Bills. It might even be supposed that the County Council calculate on this, and have no desire to purchase the undertakings. It may suit the policy of the Council by-and-bye to plead that the Companies refused to come to terms, and that there is no alternative but to introduce an independent supply. Or it may be the other way, and that the threat of a huge project, to make its appearance a year later on, is designed as a menace to force the Companies into a surrender of their undertakings on a greatly reduced valuation. The Council may not adhere to all the terms laid down in their statutory notice, and if the Bills contain such terms these may be partially abandoned. But of such moderation there are no indications at present, although there is a party in the Council who disagree with the Bills.

While the intentions of the County Council with respect to the water supply of London are invested with a considerable amount of uncertainty, the water companies are moving in a manner which leaves no room for doubt. The East London, the Southwark and Vauxhall, and the Middlesex Companies each obtained power in the past session for the raising of new capital and the enlargement of their works. The Lambeth and the Chelsea Companies are now coming forward with Bills for a similar purpose. The need for action appears very conspicuously in the case of the East London. Their proposed extension was strenuously opposed in two sessions by the County Council, and even by the Government. Now that the East London Bill has been carried, and the works are about to be commenced, the County Council turn round and accuse the Company of having, at the present time, a deficient supply. For this the Company are less to blame than the Council, though in reality a falling-off in the rainfall has precipitated the crisis. All will be right in due time, unless the Council succeed in getting possession of the works, when it is difficult to say what will happen. It is rather curious that a scheme emanates from the City authorities which goes rather ahead of the County Council. The Commissioners of Sewers have an artesian well, by means of which they are able to supply water to their artisans' dwellings in Petticoat-square. They have now given notice of a Bill by which they propose to establish baths and washhouses, and to supply these, as well as "buildings," with water, heat, and electricity. Their supply of water will doubtless come from the well, and it will be interesting to know, when the time arrives, how far this supply is to extend. Of course, none of it can be sold, and at present the Commissioners have no power to break up the streets for the purpose of laying water mains. The scheme is an interesting one, but, if the Bill proves to be designed for aggressive purposes, it will infallibly encounter the decided opposition of the New River Company. The County Council claim that no water company in London has the power to exclude any other company or body from introducing a competing supply. This is one of the questions which their eight transfer Bills propose shall be taken into consideration by the arbitrators. In fact, if the arbitrators take into consideration all the points laid down for them, it would seem as if their labours would be of an unusually protracted nature.

A statement prepared by the Corporation shows that in 1606 that body obtained an Act of Parliament, which empowered the mayor, commonalty, and citizens of London, and their successors, at any time, to open a trench for the purpose of bringing a fresh stream of running water to the north parts of the city, from Chadwell and Amwell, in the county of Herts. But "instead of undertaking the work, and reaping the benefits therefrom, on their own responsibility, the Corporation deputed the enterprise, after a lapse of three years, to Hugh Myddleton, citizen and goldsmith." The enterprise resulted in the ruin of the unfortunate goldsmith; but a Royal Charter was granted, by which Sir Hugh Myddleton and his co-adventurers were incorporated as the New River Company. The history of this undertaking shows how the municipal authority drew back from an enterprise which threatened to be costly and troublesome, and how London owed its first set of waterworks to private energy. The Corporation might have held the New River supply, whereas now, through the medium of the Commissioners of Sewers, they seek, if possible, to compete with it, and the County Council desire to buy it up at the cheapest possible rate. Many other enterprises in London are passing through a similar experience. When they were struggling concerns, reaping little or no profit, they were left to fight their own battle. But now they can pay a dividend, it is proposed that they shall be "municipalised," which means that a local authority shall step in to appropriate private profits. Under these circumstances, there is danger that local authorities will be left to undertake initiatory work, and private capital will stand aloof. How the world is to get on under such conditions, another generation may declare.

## THE MACHINERY OF WARSHIPS.

The excellent paper read by Mr. Durston before the Institution of Civil Engineers on the 20th of November, supplies more information of a kind concerning marine engines than any other written since Mr. Marshall's standard paper, read at the Newcastle meeting of the Institution of Mechanical Engineers several years ago. We have already published the only abstract of Mr. Durston's paper allowable under the rule of the Institution; but that abstract gives but a scant and inadequate notion of the great mass of information collected by Mr. Durston into tabular form. Although, as we have said, we are in great measure debarred from dealing with the paper in any comprehensive way, there are certain facts and statements which may be reproduced here without any breach of faith. These we take at haphazard as they suggest themselves.

One of the first is, that a very considerable number of ships in the British Navy are still running with compound engines, and it is interesting to compare one of these with more recent vessels. All the "Admirals" have compound engines, their average horse-power on natural draught is 8277, under forced draught 11,271. The average weight of the machinery is 1209 tons, the boiler representing 667·6 tons of this weight. With natural draught we have 6·8-horse power, and with forced draught 9·8 indicated horse-power per ton. The indicated power per foot of grate is 10·4 and 14·2, and the heating surface per horse-power is 2·4 square feet by 1·8 square inch. These figures deserve particular attention. We may note further that there is a very great similarity of dimensions, &c., among all the "Admirals." They have vertical 3-cylinder compound engines with twin-screws running about 100 revolutions per minute at full power. Stroke, 3ft. 9in.; piston-speed, 750ft. per minute. The engines of the Collingwood make 95 revolutions per minute; 3ft. 6in. stroke; piston-speed, 665ft. per minute. Their boilers are of the single-ended return-tube type, twelve in number, with three furnaces in each. The load on the safety valves is 90 lb. per square inch. The Anson has eight four-furnace boilers carrying 100 lb. pressure; the boilers are placed in four compartments, arranged back to back against a middle-line bulkhead. The ratio of the cylinders is about one to four. Unfortunately Mr. Durston in no place states the consumption per indicated horse-power per hour of any of these ships. We believe, however, that we shall not be far from the truth if we give it as 2½ lb. for natural draught, and 3 lb. for forced draught. This, of course, is understood to include auxiliary machinery, such as fan engines, steering gear, electric lighting, &c. We may now compare these figures with those relating to the machinery of more recent vessels, such, for instance, as the Empress of India, one of eight, all alike, first-class battleships, with vertical 3-cylinder triple-expansion twin-screw engines, designed to run at 108 revolutions per minute at full power, 13,000 indicated horse-power. Stroke, 4ft. 3in.; piston-speed, 918ft. per minute. The valve gear and propellers—except in Royal Sovereign—are arranged to work at a maximum effort of 11,000 indicated horse-power in order to obtain more economical results at ordinary rate of working. The boilers are of the single-ended return-tube type, eight in number, in four compartments arranged back to back against a middle-line division. Each boiler has four furnaces with two, three, or four combustion chambers. The load on the safety valves is 155 lb. per square inch.

Here we have the most modern engines to compare with those eight or ten years old. The Empress of India indicated, with natural draught, 9508-horse power; with forced draught, 11,625-horse power. The total weight of machinery and boiler is 1149 tons, of which the boilers represent 581 tons. The indicated horse-power per ton is 8·2 and 10·1. The heating surface per indicated horse-power is 2·1 square feet and 1·7 square feet. Before going further, it may be well to say that the boilers named above give, with natural draught, 16·3, and with forced draught 20-horse power per ton. In the Admiral class they give 12·4 and 16·9-horse power to the ton, on the average. The Anson has, however, given 13·5 and 20·5 indicated horse-power per ton. It will be seen, then, that the net gain due to the use of higher pressures and higher expansion engines, as regards the boilers, is about 8-horse power per ton at forced draught, and about 4-horse power per ton at natural draught, or not far from 20 per cent. This is very well worth having. But when we turn to the machinery complete, we find that while the Empress of India has 8·2 and 10·1 indicated horse-power per ton, the Howe has 6·6 and 11·8 indicated horse-power, while the Anson has 7·2 and 10·9 indicated horse-power. Thus, at forced draught both these ships beat the Empress of India, and the Howe, indeed, beat the Royal Sovereign, which indicated 13,363-horse power—to the great detriment of her boilers, be it added. It would seem, therefore, that there is really very little to choose between the triple and the compound engines on the score of weight as a whole. So far as can be gathered, indeed, the facts seem to show that in the Navy the principal benefit conferred by the use of triple-expansion engines is a saving in coal. We learn from Mr. Durston that the Royal Sovereign, on a passage from Plymouth to Gibraltar, maintained 8180 indicated horse-power for seventy-two hours, the coal consumed being 1·84 lb. per indicated horse-power per hour. The Royal Arthur, on a passage from Callao to Coquimbo, maintained 8821 indicated horse-power for seventy-two hours, with a coal consumption of 1·85 lb. per indicated horse-power per hour. The Sans Pareil, on a passage from Malta to Volo, developed 7051 indicated horse-power for fifty hours, with a coal consumption of 2·23 lb. per indicated horse-power per hour. The Sirius, on a passage, maintained 4555 indicated horse-power for sixty-four hours, with a coal consumption of 2·03 lb. per indicated horse-power per hour. The Pallas, on a passage, developed 3620 indicated horse-power for seventy-three hours. The Royal Arthur is a first-class cruiser, 10,517 indicated horse-power; the Sirius is a second-class cruiser; the Sans Pareil is a first-class battleship. These all have triple-expansion engines.

The question arises whether, considering the conditions under which the engines of ships of war are worked, it is worth while to use triple-expansion. It is perfectly well understood that, unless engines of the kind are worked at just the right power, they are wasteful of fuel. This is the reason why the valve gear has been so set that, with the exception of the Royal Sovereign, the maximum forced draught power cannot be got. Mr. Durston, in speaking of the Mersey and Severn second-class cruisers, with compound engines, points out that the ratio of the cylinders—one to 2·8 or 2·9—is not sufficient in one sense, the size of the low-pressure cylinders being too small for full power, but at the reduced powers developed on ordinary service a fair ratio of expansion can be used, and there is a certain amount of weight saved—an important item. It appears to be worth considering whether the principle might not be pushed a little further. Unfortunately we have not sufficient information as to cruising coal consumption to be able to speak with certainty, but it is fair to ask whether an adequate return all round has been got for the triple-expansion system, as compared with the compound. Furthermore, saving in space and weight being of such vital importance, might it not be worth while to inquire into the merits of Mr. Asplin's system, as fitted to Messrs. Leyland's ships with, we understand, very great success. Mr. Asplin simply omits the intermediate cylinder in a triple-expansion engine. In other words, he builds a compound engine with cylinders in the ratio of about 8 to 1. It is evident that if the system will answer in other ways, its adoption would save a great deal of space and weight in an engine-room.

Concerning the vexed question of forced draught and leaky boilers, we find Mr. Durston stating in effect that the difficulties have been overcome partly by the use of ferrules, partly by the use of pure water. But, we may add that, effectual as these may be, they are as nothing compared with the reduction of air pressure to a maximum of 1in. of water. That is the principal reason why forced draught is successfully used in the mercantile marine. The experiments with Martin's induced draught have resulted on the whole satisfactorily. Mr. Durston tells us that it does not ensure immunity from leakage, but that it gives a cool stokehold, saves fuel, and is so satisfactory in other ways, that the system is to be fitted in one of the new first-class battleships now being built, and also in a gunboat. Mr. Martin certainly deserves the measure of success he has achieved. Probably the result obtained in the battleship will be even better than Mr. Durston anticipates.

### MEASURING WATER IN STEAM.

Any of our readers who have made themselves acquainted with Professor Unwin's paper on "Priming," which appeared in our issues for Sept. 7th, Aug. 21st and 28th, can scarcely have failed to arrive at the conclusion that no accurate method of ascertaining the percentage of water in steam as it leaves a boiler exists, at all events in a shape available for ordinary use by engineers. This is extremely unsatisfactory. It is highly important that dry clean steam should be supplied to engines; and ignorance concerning the quantity of unevaporated water that leaves a boiler through the steam-pipe vitiates experiments intended to determine economic efficiency. Rightly or wrongly it has come to be understood that all boilers supply more or less wet steam—the percentage varying between about three for very good and fourteen for very bad boilers; if the latter percentage is exceeded the boiler is said to prime. If it is not exceeded, then it is said that the steam is more or less wet. Recent inquiries appear, however, to have resulted in proving that all these figures are in excess of the fact, and that most boilers are giving off dry saturated steam, and that under comparatively trying conditions. On the other hand, it is known that the engines using this steam are more or less drowned, and that from the high-pressure cylinder especially it is difficult to get a diagram which does not show the presence of volumes of water. The very natural conclusion arrived at is that the calorimeter or the salt test is entirely wrong, and give erroneous conclusions. That is pretty much what Professor Unwin's paper concedes.

In the United States a great deal of attention has been given to the subject, and it seems to be taken for granted that the Barrus calorimeter is, when *properly used*, fairly accurate. The words which we have italicised have an application beyond the Barrus calorimeter. In the difficulty of using any form of calorimeter properly, must, we think, be sought the principal cause of the unsatisfactory and untrustworthy results that are so often obtained.

The first and paramount difficulty lies in getting the sample of steam. If it is drawn from the centre of the steam pipe, it is objected that the water is really to be found on the sides and bottom of the pipe, and so escapes the calorimeter. We have ourselves seen a stop cock opened on the side of a steam pipe, the stem of the cock projecting well into the pipe. The steam coming out through the cock was apparently dry, yet further on a separator was removing water in considerable quantities from the same steam pipe. If, on the other hand, the steam is taken from the bottom or sides of the pipe close to the metal, it is urged that the sample drawn off will be much wetter than the average. It is not easy to satisfy both parties. Again, it is very well known that wire-drawing steam dries it. Consequently, if the sample is withdrawn through a small orifice, it is certain to be drier than the average. As regards the salt test, that may be regarded as entirely untrustworthy, because it is by no means certain that the water found in the steam must carry salt with it.

If it were known with any accuracy why steam is wet, the difficulty of testing it would be diminished; but nothing is certainly known on the subject. There is, of course, very good reason to believe that quantities of water are thrown up into the steam space by the up-rush of the steam bubbles breaking through the surface; but then the water ought to fall back by its gravity in any quiet part of the boiler. But this bubble action does not cover the whole ground. If any of our readers will boil clean water in a clean earthenware pipkin, they will see that there is continually flung up from the surface, what may not inaptly be termed "water dust," a multitude of excessively small spheres of water. They do not seem to have anything to do with bubbles. Indeed, they may be seen to rise before ebullition begins, and they are apparently projected upwards with considerable violence. We are not aware that this phenomena, which is very interesting, has ever attracted the attention of any physicists. It seems to be the result of some surface action of repulsion in the heated liquid. Now if the water dust does not find its way back but remains suspended in the steam, it may very well represent a considerable percentage of water, while it is by no means clear that it would carry any salt with it. But further, we may ask if it is quite certain that steam once made shall always remain steam while in the boiler? There are many reasons why it should not. Thus, although the pressure in a boiler is practically the same throughout, the temperature certainly cannot be. Not only does the feed-water come in at a lower heat than at which evaporation is taking place, but the boiling water is hotter in some places than in others. But steam is to the last degree sensitive to change in temperature, and it seems to be quite possible that steam produced in one part of a boiler may be condensed in another; the extremely fine mist resulting remaining in suspension in the steam, and being carried away with it to the engine. This action could not in any way be detected by salt.

In 1888 Mr. J. E. Denton, of Hoboken, read a very interesting paper on "The Identification of Dry Steam" before the American Institution of Mechanical Engineers. He carefully investigated—by the aid of photography, among other expedients—the appearance of steam jets. The conclusion at which he arrived is that dry steam, if allowed to flow into the atmosphere through an orifice under such conditions that it attains its maximum velocity at about the instant of exit into the air, is invisible for a very short distance from the orifice. The slightest obstruction to its outflow created by throttling, superheats the steam, and less than five degrees produces a considerable increase in the length of the invisible portion of the jet. The jet is similarly sensitive, in a reverse way, to the presence of moisture, as little as 1 per cent. causing distinct whiteness in the jet over that portion which would have been blue had no moisture been present. Mr. Denton holds that, with proper precaution, the tub calorimeter gives the most accurate results. But he adds that if a stop-cock be fitted on the steam pipe, and the jet is transparent close to the orifice, or even a greyish white colour, the steam may be assumed to be so nearly dry that no portable tub apparatus will detect the true percentage of moisture present. In all cases he advises that the pet cock should be fixed on the boiler; if put on the pipe it may give deceptive results, due to condensation in the pipe. In using the tub, the weight of condensing water ought not to be more than thirteen times the weight of steam condensed, and the range of temperature not less than 85 deg.

On the whole, when considerable quantities of steam are dealt with, and adequate appliances are available, nothing, in our opinion, can be more trustworthy than this well-known system of blowing a given weight of steam into a tank or tub. The precautions to be observed are, after all, not very troublesome. The end of the tube opening into the cold water tub ought to be fitted with a spring-loaded valve, so that the water may not be blown out of the tub, as commonly happens. The tub should be carefully felted to prevent loss of heat, and should hold a good deal of water—certainly not less than twenty gallons. A special thermometer with long range ought to be used, and the whole experiment should, in a word, be carried out on a scale sufficiently large to reduce the importance of small errors to a minimum. Whether our readers do or do not agree with us in these suggestions, they will have to admit that no perfectly trustworthy system of measuring the dryness of steam is now available to settle disputed questions as to the merits and demerits of boilers. And this is such an unsatisfactory position of affairs that the whole subject should be carefully and fully discussed with a view to setting it on a better footing.

◆

### INSTABILITY OF FRENCH BATTLESHIPS.

A few months ago a great deal of criticism was passed in France upon the behaviour of the battleship Magenta, which gave alarming signs of instability, and necessitated some costly alterations before the vessel could be considered at all seaworthy. Nothing definite was ever made public as to the causes of the Magenta's instability, or as to the nature of the improvements that had to be carried out. Official prudence inclines rather to minimise any such untoward occurrences, so that the public may not be unduly alarmed at the increased expenditure. In any event, it might have been thought that the experience would have served as a lesson to French designers in the future. So far is this from being the case that the very same defects have become noticeable in the battleship Brennus, which recently left the Lorient Arsenal for her official trials at Brest. While on the voyage the vessel behaved in a very alarming manner, and, according to the official explanation, this was due to the exceptionally bad weather and the heavy seas. During the trials the vessel listed over to such an extent that it was feared she would turn turtle. The water came rushing in at the port side, and for a moment there was a panic on board. The men were then mustered on the starboard side, and the vessel righted herself. It is stated in the official communications that the unsatisfactory results of the trials have been much exaggerated, and that no proof has been afforded of the instability of the Brennus. The vessel, it is said, listed over eight degrees, which was quite sufficient to let the water in at the open port holes. Had these been shut there would have been no cause for the sensational rumours now afloat. This explanation is hardly likely to satisfy the critics in view of the fact that the official authorities have considered it necessary to carry out extensive alterations which will involve an expenditure of something like £16,000. It is stated that the defects are caused by the overloading of the deck with constructions that had not been provided for in the specification, and that consequently the responsibility rests with the authorities at the Lorient Arsenal. Whether or not there is any truth in this statement, it is certain that it has been found advisable to remove one of the armoured masts and reduce the others, so that there would seem to be something more in the defects than the additions made to the upper structure by the arsenal authorities upon their own responsibility. The alterations to be made will occupy a twelvemonth, so that instead of the Brennus joining the Mediterranean squadron on the 1st of January next, she will not be ready until the beginning of 1896.

### NEW CLYDE RIVER BOATS.

On the Clyde, next summer, apart from yacht racing, the appetite for nautical sensations is likely to be fully whetted. During November no fewer than four contracts for fast river passenger steamers have been placed with rival Clyde builders. The most important order is that for a new vessel for the Caledonian Steam Packet Company, entrusted to Messrs. J. and G. Thomson, Clyde Bank. The guaranteed measured mile trial speed of this vessel is said to be eighteen and a-quarter knots, which might not be considered abnormal were it not for the stiff conditions with which its attainment is said to be hedged round. These are concered with boiler power, air pressure in the stokehold, &c., and a number of Clyde builders are declared to be of opinion that this new steamer is a stiff nut to crack. Another of the orders is for a steamer for the North British Railway Company, which Messrs. Barclay, Curle, and Co., will build and engine, and which owners and builders alike intend shall be a "flyer." A third order is for a first-class paddle saloon steamer, to be built for Mr. John Williamson, for service between Glasgow and the Kyles of Bute. Messrs. Russell and Co., Greenock, will build the hull, and Messrs. Rankin and Blackmore, Greenock, will supply engines of a specially economical type. The fourth order is for a Bristol Channel boat, secured by Messrs. Hutson and Son, Kelvinghaugh Engine Works, who will engine her, the hull being built at Alloa by Messrs. H. McIntyre and Co. She will be a repeat of the Westward Ho, completed by Messrs. Hutson and Son last year for the same service. In the case of the new vessel, the owners have publicly stated she is to be one of the handsomest and fastest river steamers afloat.

### THE NORTHERN CHEMICAL CRISIS.

In the north-east the chemical manufacture is evidently approaching a crisis. The notices to terminate the employment of some thousands of persons employed in the manufacture are running their course; and whilst the beginning of the idleness antedates only a little the usual year-end holidays, it is now officially stated that the resumption of work will depend on the acceptance by the workmen of certain reductions in wages. It is, we believe, the fact that three or four years ago the trade was comparatively brisk, and advances in the rate of pay were made, in some instances voluntarily, and in others in response to claims on the employers by the men. Since that time the price of many of the products of the factories has gone down considerably—the fall in soda crystals being about 40 per cent., with a declining tendency still; and the employers naturally wish to reduce the cost of production in some degree. It is now becoming apparent that the competition between the two methods of manufacture—that by the old Leblanc process, and that by the newer ammonia process—are beginning, in the present dull condition of the general manufacturing industries, to make certain kinds of chemicals so plentiful that low prices are needful to enable them to be sold. America, it was thought, would greatly increase her orders when the tariff unsettlement was removed; but although this has to some extent been the case, the recovery is an incomplete one, partly because of the intense depression in the trade of the United States, and partly because of the constant endeavour to enlarge her own producing facilities. On the European Continent, too, the production of alkali is being enlarged, so that our manufacturers find that it is imperative to reduce the cost of production if they are to retain some of the markets they have been wont to supply, and to make any profit out of their produce. On Tyneside the production is exclusively by the old Leblanc process, and it finds very keenly the critical state of the trade, as may be readily seen when it is added that the number of the alkali works in operation there is now only about a third of what it was a few years ago, though probably the production of the operative works has been increased. Thus the issue of the choice that has been put before the workmen in the northern chemical trade is one that will be looked forward to by all who are interested in the alkali manufacture, and in its English birthplace.

### THE YEAR'S SCOTTISH SHIPBUILDING.

Eleven months of 1894 having now passed, an accurate estimate may be made of the output of new shipping in Scotland for the whole twelve months. During the eleven months, tonnage to the extent of 325,000 tons has been sent off the stocks, and from observations taken as to the vessels still in the yards and nearing the launching stage, the year's output may safely be set down at 345,000 or 346,000 tons. This result is an advance on last year's output by about 65,000 tons, but forms exactly an average figure for the past five years. Of the total, the Clyde alone is to be credited with 315,000 tons, leaving a small proportion indeed to the credit of the Forth, the Tay, and other Scottish centres.

## LITERATURE.

*The Electric Current.* By R. Mullineux Walmsley, D. Sc. (London), F.R.S.E., &c. Cassell and Co., London, Paris, and Melbourne. 1894.

*Electric Lighting and Power Distribution.* By W. Perren Maycock, M.I E.E. Whittaker and Co., London. 1894.

*Electric Light Installations.* By Sir David Salomons, Bart., M.A. Vol. III. Whittaker and Co., London. 1894.

We recently had occasion to review a book—"Electricity in the Service of Man," Cassell and Co.—edited and partially rewritten by Dr. Walmsley. The present work strongly resembles the former, but we suppose that the author has felt less hampered when writing a work of his own than when dealing with that of another. The work extends to 754 pages, and the subject is treated as far as possible without the aid of mathematics, the object being to enable the lay reader to understand as much as possible of the modern uses of electricity. The author's position as Professor of Applied Physics and Electrical Engineering at the Heriot-Watt College, Edinburgh, and his earlier experience as principal of the Sind Arts College, Bombay University, have undoubtedly given him valuable experience in this branch of education. The book is well illustrated with 379 figures.

After a brief but carefully written historical sketch of the growth of the science, the author proceeds to describe the methods available for the production of the electric current. The subject of primary batteries is treated with sufficient fulness for the lay reader, and the book is not burdened with descriptions of numbers of obsolete types of cells. The subject of magnetisation is dealt with, and the curves obtained by Professor Ewing are explained. The author acknowledges his indebtedness also to Professor S. P. Thompson. In the description of the thermopile the small commercial efficiency of this class of apparatus is pointed out. Taking the Gulcher thermopile, which was exhibited at the Frankfort Exhibition, as about the most efficient yet produced, he shows that the same quantity of gas, if used in a gas engine and employed to drive a dynamo, would produce about 18½ times the electrical energy produced by the thermopile.

Very considerable space is devoted to descriptions of measuring instruments. Telegraphy is then touched upon, and the subject of the transmission of power and the public supply of the electric current treated. It is of course out of the question, in the space occupied, to treat such a large subject in detail; but the author has produced a work which should assist the general public to comprehend more clearly the principal facts of the science of electricity. If journalists occupied upon the daily papers were to read such books, it might result in more lucid paragraphs dealing with electrical matters.

Mr. Perren Maycock states that, in his work as a teacher under the City and Guilds of London Institute, he knew of no really reliable elementary work which he could recommend to beginners in his classes, and therefore has tried to supply the want. The work originally appeared in three parts, the present volume consisting of the three parts bound in one as a second edition. The author is indebted to Mr. James Swinburne for the revision of proofs and valuable suggestions. The book is written with a view to the syllabus of the City and Guilds ordinary grade examination, and at the end of each chapter there are numerous problems, to be worked by the student. It is intended for use in classes, and there is a savour of the payment-on-results system, which is perhaps difficult to avoid. When a teacher is obliged to rely upon a certain percentage of passes—for pecuniary profit—he cannot afford to illustrate his subject by showing the gradual life history of the various apparatus he describes, but is driven by the ever-present syllabus to sacrifice everything which does not appear calculated to lead to "marks." The book, however, is carefully written and well printed; but some of the illustrations are rather crude sketches.

As the book was originally published in three separate parts, with a table of contents in each, three tables will now be found at different points in the volume. It would seem preferable to collect these at the front, as the work is paged continuously throughout.

The third part of Sir David Salomons' book is now before us. The first two volumes have already received notice, on p. 409, Nov. 9th, 1894. The present volume deals with the application of electricity. In the first chapter the author gives a needful caution to persons desirous of using the electric light, and suggests that a consulting engineer should be called in just as an architect is applied to if a building is required. The far too common practice appears to be to obtain tenders from contractors, and then to find that such tenders cannot be compared with one another, and finally to call in an independent engineer to revise such tenders, or to leave the work entirely in the hands of the contractor. The author points out that the alternate current is far more dangerous than the direct current. For example, he states that there can be no doubt that "an alternate current of 100 volts suitably applied to the human body may prove a death current, whereas a direct current of 600 volts does no harm at all." The susceptibility of different individuals, however, varies greatly, for a person with a naturally dry skin may handle with impunity terminals of an alternate current circuit, which another with a naturally moist skin could not touch without experiencing a shock.

The author distinctly favours paper insulation for conductors as likely to prevent decentralisation of the core, which is liable to occur with rubber insulation if the conductor becomes hot through carrying too large a current. But he states that at present no opinion can be formed as to the lasting character of the paper. With a view to avoiding the evil effects upon the eyesight of clear glass lamp bulbs, the author advises the use of ground glass bulbs only, and we quite agree with the view that a diffused light is best, and that the use of lamps or lights of any kind with shades which cause an intense illumination to be thrown upon any object, while the eyes themselves are in the shade, is a mistake, as it causes unnatural strain upon the iris. The chapter upon testing for insulation is exceedingly clear, and we do not doubt that it is advisable for all persons using the electric light to cause periodical tests to be made as to the state of the wiring, and in this way fires caused by leakage would be avoided.

The book is a valuable addition to the literature of the subject; the author has had so much practical experience that his advice is perfectly sound. In the chapter upon alternate currents he passes beyond the usual bounds of the practical application of the science, and suggests the view that life itself may be a phase of electrical energy; but he is careful to point out that what is said must not be regarded as necessarily his personal views upon the subject, nor must the argument be considered from a religious or irreligious standpoint. Should the existence of life be at any future period proved to be an electric phenomenon, all questions as to whether revealed religion is true or not would in no way be affected.

*Practical Electrical Engineering. A complete Treatise on the Construction and the Management of Electrical Apparatus as used in electric lighting and electric transmission of power.* By various writers. Edited by C. H. W. Biggs, M.I.E E. London: Biggs and Co. Vols. I. and II. 1894.

The first of these volumes contains chapters on general electrical principles and the conductive and inductive circuits and the magnetic circuit, and on electrographics, in all of which the hand of the editor is traceable. Other chapters are on the central station and on foundations considered with reference to the class of machinery used in electric supply works. These are followed by a long section on boilers and boiler fittings, which, though elaborate and painstaking, does not quite meet the requirements of electrical engineers, as it is, on the one hand, too much on the elements of construction, and, on the other, too much merely descriptive of fittings, unnecessary space being given to such things as engravings of donkey pumps. It is also a question whether textbook matters do not take up rather more space than is necessary in the chapter on heat, and, although in itself satisfactory, it is like the chapters on the steam engine, so much of the nature of that which every engineer prefers to look for in the special text and reference books, that it seems somewhat out of place in a work which one would expect would more especially contain those things mechanical, electrical, and critical, which concern the practical engineer in connection with the application of mechanical and electrical engineering knowledge already obtained, in the generation, measurement, and sale of electricity. Our impression as to the requirements, and the promise which is implied in the title, lead us to remark that no chapters in a work of this kind can take the place of the existing standard books on heat for the steam engine and steam boilers, nor are such chapters implied. When, however, we have passed these chapters and reach those on electrical measurement, on switchboards and switches, and on electric light mains, we find what must be looked upon as legitimate and useful parts of the book.

In the second volume we have a valuable addition to the existing literature of practical electrical engineering. The first part deals in fourteen chapters, occupying ninety-seven pages, with the theory and construction of dynamos, alternators, and transformers, and will be recognised as an able treatise on these subjects, and one which will be constantly referred to by the learner as well as by those engaged in these branches of electrical engineering. This part is followed by six chapters, occupying seventy-eight pages, on secondary batteries, and as these contain not only a general description of the construction and electro-chemistry of these batteries, but a useful chapter on the employment of secondary batteries in central stations, they form a valuable part of the work, for although secondary batteries have never achieved all that was expected of them, they form an important portion of the plant in many installations. The design of conductors for distribution, including distributing mains and the various questions concerned in the design and proportions of net works of mains and feeders, occupy the next chapters and 66 pages, and these are followed by chapters on one of the most interesting of electrical subjects, namely, electric transmission, occupying 122 pages. Electric transmission of power and distribution, traction data, energy consumed, and load diagram, form the subjects of the second of this section, and their treatment will be recognised, when taken with the questions dealt with in the third chapter, as of practical value. It may perhaps be noted that there is a little inconsistency in the two following paragraphs found in pages 252 and 257. Speaking of the energy consumed on electrical tramways, the writer says, "therefore it may be safely assumed that a motor which is capable of propelling the car on any road will also be powerful enough to start it in every part of the line, provided that the magnet coils are joined in series with the armature, and provided also that the supply of current from the generator accords with the requirements of the motor." "If we calculate from the accepted coefficients of resistance to traction on common tram rails, we find that an ordinary tramcar will require but 3 to 4-horse power when once in motion. But it is the setting of a vehicle in motion from a state of rest which demands the greatest amount of energy; and the electric motors which were built in the early days were soon knocked to pieces by the enormous strain put upon them at starting." And further on we read:—"The maximum current used was 70 ampères at starting; on the curve or grade it rose to as much as 120 ampères. The average current consumed was 22·6 ampères." Other remarks, which we need not quote, prove that in practice the motor power which would be sufficient to propel a car six miles an hour, will not be sufficient for the other requirements of tramcar operation. Some very good engravings are given of the underground conductors and permanent way of some electrical street tramways at work, and of others which had been under trial; and the parts on traction by overhead conductors is interesting. With reference to the papers by Mr. H. D. Wilkinson, now under discussion at the Institute of Electrical Engineers, the particulars given of the generating stations, road curves, and cost of electric traction in America and elsewhere, form a valuable part of the book. Chapters on incandescent lamps and arc lamps, their construction, consumption, arrangement, and cost, complete the volume.

## *BOOKS RECEIVED.*

*Annual Report of the Board of Regents of the Smithsonian Institution.* Showing the operations, expenditures, and condition of the Institution to July, 1893. Washington: Government Printing Office. 1894. — A valuable collection of papers on scientific subjects, some of which have appeared in other places in this country, with illustrations.

*The Mechanism of Weaving.* By T. W. Fox. Price 7s. 6d. London; Macmillan and Co. 1894.—This is an octavo book of 472 pages. Fairly well illustrated, and supplied with a good index, it has been written in the cause of technical education, and to give the workman of the present day, say a weaver, some information concerning the construction of looms in general, and the principles of their action. The illustrations given were prepared from machines now in the Municipal Technical School, Manchester.

*Thirteenth Annual Report of the United States Geological Survey to the Secretary of the Interior*, 1891-92. By J. W. Powell, Director. In Three Parts. Part I., Report of the Director. Part II., Geology. Part III., Irrigation. Washington Government Printing Office. 1893. These handsome volumes contain papers on hydrography and irrigation on the American Continent, and an elaborate description of the canal system in India, which cannot fail to be of interest to all engineers engaged in this class of work. The illustrations are excellent and abundant.

*Proceedings of the Incorporated Association of Municipal and County Engineers.* Vol. xx. 1893-94. Edited by Thomas Cole, Assoc. M. Inst. C.E. London: E. and F. N. Spon. 1894.—We have in this work a series of papers on subjects interesting to county and municipal engineers. There is neither index nor contents. The papers deal with such matters as breaking up Macadam, wood paving, electric lighting, water and sewage works. The discussions were carried on by those qualified by their position and attainments to speak with authority.

*Proceedings of the Twenty-seventh Annual Convention, American Institute of Architects, held at Chicago July 31st and August 1st.* 1893. Published by the Board of Directors, A.I.A. Alfred Stone, editor. Chicago: Inland Press-office. 1893.—Contains papers on the construction of the buildings of the late Exhibition at Chicago, the transport and power and electrical plant there; accoustics in building, architectural style in the United States, ethics in architecture, recent plumbing practice, use of colour in architectural design, foundations of high buildings, fire-proof construction, architectural engineering, library buildings, and on other subjects.

*The Thumb Ready Reckoner. Containing calculations from one sixteenth of a penny to nineteen shillings and ninepence, &c.* Price 1s. London: Henry Frowde. 1895.—This tiny volume contains 640 pages, measures only 2⅛ by 1⅞ inches, and weighs less than an ounce. The figures are all clear and distinct, type having been specially cast. The interest tables give the percentages most generally required; and, with the discount tables, show in a compact form calculations which have to be made daily in every counting-house. The metric system is fully described; together with comparative tables of English and French weights and measures, showing at a glance the value of inches in centimetres, pounds in kilogrammes, &c.; the values of foreign money, and a postal guide are also added. A little case for the book would be useful.

*The Student's Cotton Spinning.* By Joseph Nasmyth. Manchester: Of the Author, 61, Barton-arcade; and of John Heywood, Manchester and London.—This is the second edition of a book which has removed a want previously existing. The chapters are on the evolution of cotton spinning and the distribution and varieties of cotton; mixing, opening, and scutching; carding, combing, and drawing; mule and ring spinning; manufacture of thread; waste spinning; and the construction of mills. The book thus covers a wide range not covered by the author's book on "Modern Cotton-spinning Machinery," but it may be questioned whether the part concerning steam engines is either looked for or the information wanted, or, if wanted, not much provided by books on steam engines and not on spinning. The book is a valuable one even if nothing is allowed for this part of it, and it conveys to the student clear ideas on the many complicated processes it explains.

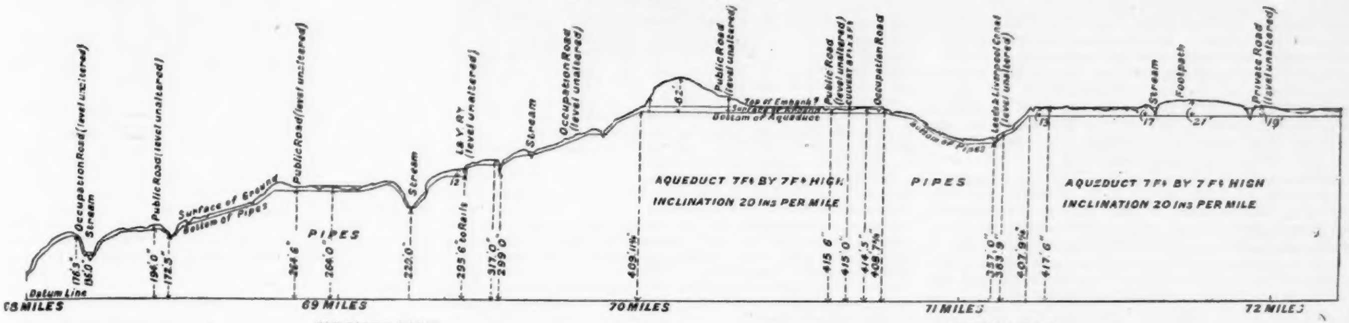
# THE MANCHESTER THIRLMERE WATER SUPPLY AQUEDUCT

(*For description see page* 479)

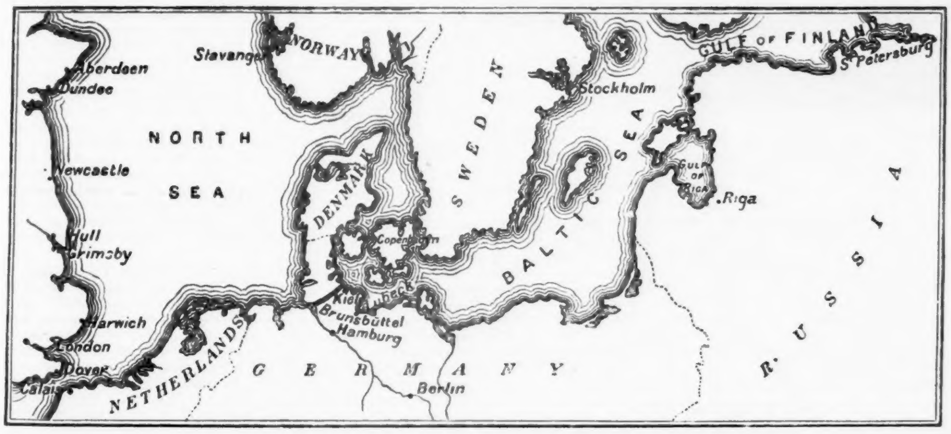


## FOREIGN SHIP CANALS.

The present seems to be the era of canals and shipways. No sooner was the Manchester Canal undertaken than other schemes for securing similar advantages came up for discussion and promotion. Some comparison of these may be of interest. Two of these later schemes, which are now approaching completion, viz., the Baltic and North Sea Canal and the Chicago Canal—of the latter of these we recently gave a short account, and of the former we published an account in The Engineer, vol. lxxvi., p. 326—are works of great importance and magnitude, and present features of general interest to the profession. The annexed table gives the leading features of these three canals, and also of the Suez, so that a comparison may readily be drawn without trouble:—

| Name of canal. | Length in miles. | Depth in feet. | Bottom width in feet. | Surface width in feet. | Passing places. | Number of fixed bridges over canal. | Headway for masts under ditto. | Number of swing bridges over canal. | Years in construction. | Cubic yards of excavation in all materials. | Cost of scheme in pounds sterling. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| Manchester .. | 35½ | 26 | 120 | 172 (average) | None | 7 | 75 | 9 | 6 | 53½ million | £15,000,000 |
| Baltic.. .. .. | 62 | 30 | 86 | 217 | 7 | 2 | 140 | 4 | 7 | 69 million | £8,000,000 [estimated |
| Chicago .. .. | 29 | 23 to 26 | 160 to 200 | 162 to 300 | None | — | — | — | Not finished | 36 million | Not finished. |
| Suez .. .. .. | 100 | 26 | 72 | 150 to 300 | 18 | None | — | — | 10 | 80 million | £20,000,000 |

*The Baltic Canal.*—The accompanying map will show at a glance the position and object of the Baltic scheme, and indicates at once the great facilities which the canal will offer to all vessels trading with Baltic ports. At present the natural and only entrance to this sea is by the canal Skagerack, and through the sinuous channels dividing the East Coast of Denmark from the neighbouring shores of Sweden. When we consider the dangers of this passage, and the enormous amount of shipping passing and re-passing every year, in addition to the list of vessels which are annually lost in and about the Sound, we do not wonder that at length an alternative route is being provided at the entire cost of the State. In 1877 the amount of shipping entering and leaving the Baltic was returned at 10¼ million tons, and by 1889 this great trade had increased to over 16½ million tons, and is still growing. Every year two hundred shipping disasters on an average are reported from these seas, and in 50 per cent. of the cases the ship becomes a total wreck, the crew most frequently perishing along with the vessel. The first attempt at an improved channel was made by the townfolk of Lübeck early in the fourteenth century, by cutting a short canal to connect them direct by water with the city of Hamburg. Other and more important schemes were from time to time proposed, but most of them came to nothing for reasons of a political and somewhat selfish nature. But when the provinces of Schleswig-Holstein became a part of the consolidated German Empire, Herr Dahlstroen, the engineer of Hamburg, saw that there was some hope of carrying some such project to a successful issue. In 1878 he first prepared a tentative scheme, and in eight years' time all opponents, both commercial, political, and military or strategic, had been convinced of the true value of the scheme. It is said that Von Moltke was for a long time opposed to the idea, but afterwards came to see that it had without doubt special advantages to offer in case of a prolonged naval struggle. After the plans had passed with the Reichstag and the Prussian Diet the money was raised as a State loan, and the work of construction officially commenced on June 3rd, 1887, by the late Emperor William I.—just five months before the cutting of the first sod of the Manchester Canal. Eight years was the estimated time for construction, and this, it is said, will not be exceeded, but whether the original estimate of 156 millions of marks is also "within the mark" we are not told. The canal, as we have said, is sixty-two miles long, and runs by easy bends in a north-easterly direction from Brunsbüttel on the Elbe to Holtenau, near Kiel. At each of these places entrance locks, 500ft. by 83ft., with a depth of 32ft. 6in. on the sill, have been constructed, but it is not expected that they will be called into use except on rare occasions, possibly at Holtenau, and for a short time between tides at Brunsbüttel. The engineer's scheme is that there shall be a constant flow from east to west, out of the practically tideless Baltic into the Elbe. In this way the canal itself will be kept sweet and fresh, and the steady flow, it is expected, will help to scour the channel of the Elbe, which in some places is shallow and tends to silt. The construction of the work has not been a matter of serious difficulty at any stage, the entire mass of excavation being in sand or clay, no rock being met with from end to end. Perhaps the greatest trouble to be overcome was the cutting of the channel through the Meckelmoor—a swamp or morass a few miles west of Rendsburg. However, by tipping sand from other parts of the work into the bog, the unstable material was placed under pressure and "spewed" out. The canal was afterwards cut through the comparatively dry sand which had deposited in place on the clay substratum. The normal surface width of the canal is 217ft., with a bottom width of 87ft.; but at the seven special passing places or "lay-byes" the width at surface is increased to 330ft. from side to side.



MAP OF SEAS CONNECTED BY NORTH SEA AND BALTIC CANAL

*The Chicago Canal.*—Referring shortly by way of comparison to this latest American work, we find a most curious state of things existing. The Chicago river was and is little better than an open sewer, taking all the town drainage, and discharging it into Lake Michigan or into the valley of the Mississippi as the local rainfall chanced to cause the river flow to tend. For some years past, however, the discharge of any sewage into the lake has been forbidden by the "powers that be," so the river has been given an artificial current back to the Mississippi water-shed by means of pumping at the Chicago City end. With a view to improve on this state of things, and to afford relief from flooding, the river is now being diverted, and a new drainage canal cut from Chicago to Lockport, a distance of twenty-nine miles. This is, however, only a part of the entire scheme, for it is contemplated to carry the works down the valley a further seven miles to Lake Joliet, making a total distance of thirty-six miles from Chicago. It is interesting to note that whereas in the case of the Manchester Canal one of the great arguments used by the opponents of the scheme before Parliament, was the fact of there being sewage in the river water. At Chicago the promoters are actually proposing that their "open sewer" shall be used as a navigable channel for vessels up to 22ft. draught. We dealt fully with the various aspects of this work in The Engineer, of 28th September, 1894, and only hope that no serious epidemic will result from this bold venture if ever it becomes an accomplished fact. Some critics, however, say they cannot imagine a more complete "cholera trap" than this is likely to prove during the hot months of an American summer.

## SOUTH AFRICAN RAILWAYS.

The British Consul at Beira has made a further report on the railway from Beira to Mashonaland, considering one necessary, as since the former report a wet season has passed, improvements have been made in the rolling stock, and the extension to Chimoio is well under weigh. Starting from Beira at 8 a.m., Fontesvilla was reached at 4 p.m. The railway workshops there contained a circular saw, various boring and cutting machines, and a turning lathe. About six men were at work fitting up a new locomotive and repairing others. There is a fairly large siding here, the rails running to the goods station at the river bank. Landing is effected when necessary by a six-ton steam crane. Shunting is mostly done by natives, of whom there is a staff of about fifty for station service. The passenger station, like most of the buildings at Fontesvilla, is of wood and corrugated iron. The railway ground is enclosed by a fence of barbed wire. There are two trains each day, one leaving at 7 a.m. and the other a few hours later. The early one, by which passengers usually travel, reaches the terminus about 6 p.m. The journey is performed in three stages of forty, twenty-five, and ten miles each, this method of running being rendered necessary by the unsuitability of the rolling stock. The heavy engines are not on bogies, and cannot with safety go round the sharp curves on the upper part of the line, and the smaller engines cannot take heavy loads up the inclines. The train, on starting from Fontesvilla, consisted of four goods and one passenger truck, but by the time it reached the terminus only one goods truck was left. After forty miles, even with a small engine, the train went very slowly round the many curves. Passengers are carried in a truck fitted with garden seats, and protected from sparks and the weather by a light wooden roof without sides. The line is very well laid and maintained, the trucks running smoothly even when going at twenty miles an hour on the level. Surface men are stationed at every seven miles to keep the permanent way in good order. At seventy-five miles is the camp, 1000ft. above the sea level, the headquarters of the men working on the extension. Almost immediately after the cuttings and embankments begin, and continue for about three miles, the extreme depth of the former being 40ft., and the extreme height of the latter 60ft. The soil is mostly hard gravel, and very little blasting has been required. The longest embankment is about 1000ft. long, and contains 17,000 cubic yards of material. The heavy work has to be finished and ready for the rails by the end of the month of August. Plate-laying was going on beyond, and had reached to eighty-two miles. A temporary line passing round the heavy work had been laid over a short, steep hill. Material for the plate-laying has to be carried on men's shoulders about 500 yards up-hill, that part of the temporary line being too steep for trucks. From the top of the hill trollies run of themselves towards the extension. A locomotive employed in carrying material was dragged up the hill by 200 natives. The contractor's principal office, connected by telegraph with Fontesvilla, is at seventy-seven miles. There are telegraph stations at forty and sixty-two miles. The supply of water along the line has been a serious affair. As a rule, it is pumped from wells over 60ft. deep into iron tanks at the side of the line. Wood fuel is largely used for the locomotives, being readily obtainable close to the line except along the first ten miles. The timber on alternate blocks along the line belongs to the railway company. In a few places the trees are large enough to have a commercial value, which the railway company intends to test by exporting some specimens. Between Fontesvilla and the terminus there are two wooden bridges carrying the line across the Crocodile and Mutachiri rivers, also several cuttings and embankments, but none of any size. The first run of the train driven by a traction engine to pass through that portion of the line going through the tsetse fly country was a comparative failure, no proper arrangements having been made for a water supply along the line which runs along the top of a ridge, and all water having to be carried to the engine in buckets, sometimes for a distance of 400 yards. Some days the run made did not exceed five miles. The second run was also a failure, and during the first month only thirty runs were performed, instead of 150, as was hoped for. The water difficulty still exists, though to a much smaller extent; but the contractors have great trouble with their engine drivers, who are not steady. Transport to Chimoio by wagons and native carriers was going on more rapidly than from Chimoio forward. The rates are: From seventy-five miles terminus to Chimoio, wagons, £12 10s.; traction engine, £12 per ton; natives per load of 50 lb. to 75 lb., 9s.: Chimoio to Salisbury: Wagons, £15 per ton. When the railway is open to Chimoio it is expected that the rate from Biera will be reduced from £32 10s. to £20 per ton. Very little serious damage was done to the line by the rains of 1893-4. For the line the work was most suitable. The only defects are—Insufficiency and unsuitability of the rolling stock; laying of the first part at the level of the surrounding plain, which in the wet season is flooded to a depth of 2ft. or 3ft., and the extreme steepness of some of the embankments, from which the jar of the passing train causes earth and stone to fall down. The first is being remedied, the second has not any result until the rains, and the third, it is said, will cease when the grass has grown on the banks.

## IN PARLIAMENT, SESSION 1895.

AMONG the notices already put forward is an application by the Great Eastern Railway for general powers, including the construction of a new railway and wharf or quay in the Isle of Ely, along the north-west bank of the River Nene, the old course of which is to be dredged. The company also petitions for powers to purchase additional lands in the counties of Middlesex, Essex, Suffolk, Cambridge, and the Isle of Ely, and for an extension of time for the completion of the works authorised by its Act of 1890. Under the title of Lynton and Barnstaple Railway, a Bill will be introduced for the incorporation of a company, together with the clauses necessary for entering into agreements with the London and South-Western and the Great Western Railways. Clause 2 contains a special provision, which is to authorise the construction and maintenance of the railway hereinbefore described, or any part of it, on any gauge not being less than a 2ft. gauge, and not of greater width than 4ft. 8½in., and as far as may be necessary, to exempt the company and the railway from the provisions of the "Act for regulating the gauge of railways," and to amend or repeal the Act. A Bill is also sought for by the Wrexham and Ellesmere Railway for a new line in Salop, and an extension of their loop line to Oswestry. The Fishguard and Rosslare Railways and Harbours Company ask for powers to build, work, and use steam and other vessels, and to raise further capital. The Brymbo Water, the British Gas Light—Staffordshire Potteries—and the Chesterfield Gas and Water Board are also in the list of proposed applications.

A Provisional Order is solicited for the construction of a new pier, 230 yards in length, and harbour at Minehead; and the Pontypool Electric Lighting, Notting Hill, Winchester Corporation, New Windsor Corporation, Alderley Edge, near Chester, and Swindon New Town, are all petitioning under the Electric Lighting Acts for similar Orders. The Barnstable Gas Company has likewise scheduled an application to the Board of Trade.

The recent addition of over a hundred notices for Private Bills and Provisional Orders for next session must have had an inspiring effect upon the parties concerned in the promotion of engineering projects and utilitarian schemes demanding legislative enactments. More than a third of this number are promoted by existing railway companies, as is usual, many of which require extension of powers, extension of time, and extension of capital. Among these we observe it is proposed to make a light railway—Stroud and Painswich—to be constructed and worked as such.

In London, the Metropolitan District ask for time to complete the Acton Junction line, and the City and South London desires to make an additional approach to its station at King William-street. The Great Northern and City petition for extension of time to purchase lands and complete works. In respect of projected works closely concerning the metropolis, other than railways, the London County Council has no rival. The Tower Bridge, Southern approach, is again to be brought forward, and a Bill is put forward for a new bridge over the Thames at Vauxhall. Besides asking for general powers to enable it to widen some of the London streets, the London County Council seeks separate Bills for widening the Strand and Carting-lane, and to allow them to work some of the tramways. Eight of our waterworks are to be transferred to the same authority, not to mention some minor absorptions.

Under the title of the Westminster Parliament-street Improvement, an extension of time is petitioned for, in order to allow of the compulsory purchase of lands between Great George-street and Charles-street, and between Parliament-street and Delahay-street. Powers are asked by the Manchester Ship Canal Company to alter the position of its pontoons, jetties, and workshops; and we notice the reappearance of the Dover Undercliff Reclamation, which proposes the construction of an embankment from Dover to the bay of Saint Margaret.

Among the Provisional Orders, which are increased by over a score, those applying to electric lighting far exceed all the others. There are a few relating to water supply, and one or two for the construction of piers and other marine works. In the metropolis, the Strand District and the Battersea Electric Lighting Co.'s are to the front, while in the provinces we find included in the same category towns of the size and importance of Southampton, Salisbury, Llandudno, Luton, Bath, Devonport, Margate, and others of similar calibre.

## LETTERS TO THE EDITOR.

(*Continued from page* 4o7)

### THE THEORY OF THE STEAM ENGINE.

SIR,—Mr. Cherry's proposition may be put into the following shape. The three angles of a triangle are equal to two right angles. Therefore no heat engine can have a higher efficiency than that denoted by the fraction $\frac{T-t}{T}$.

The assertion that what is known as Carnot's theorem can prove of the smallest utility to inventors or designers of hot air, steam, or gas engines, is flatly untrue. Mr. Cherry ought to know perfectly well that it is untrue. I have already shown that the fraction of the heat supplied utilised in the cylinder of a good steam engine may be double that which, according to Carnot's theorem, it ought to be. Why does not Mr. Cherry attack that statement and show wherein the error lies?

I will go further, and challenge Mr. Cherry to prove that Carnot's engine is that which will give a maximum return in work for heat expended. The so-called "proof" is most unsatisfactory. Here it is as given by Maxwell:—"Carnot's principle, then, is that the efficiency of a reversible engine is the greatest that can be obtained with a given range of temperature. For suppose a certain engine M has a greater efficiency between the temperatures S and T than a reversible engine N, then if we connect the two engines, so that M by its action drives N in the reverse direction, at each stroke of the compound engine N will take from the cold body B the heat *h*, and by the expenditure of work W give to the hot body A the heat H. The engine M will receive the heat H, and by hypothesis will do more work while transforming it to B than is required to drive the engine N. Hence, at every stroke there will be an excess of useful work done by the combined engine. We must not suppose, however, that this is a violation of the principle of the conservation of energy, for if M does more work than N would do, it converts more heat into work in every stroke, and therefore M returns to the cold body a smaller quantity of heat than N takes from it; hence, the legitimate conclusion from the hypothesis is, that the combined engine will, by its unaided action, convert the heat of the cold body B into mechanical work, and that this process may go on till all the heat in the system is converted into work. This is manifestly *contrary to experience*, and therefore we must admit that no engine can have an efficiency greater than that of a reversible engine working within the same temperatures."

It will be seen that the whole point of the "proof" hangs on the words which I have put in italics. Ther eply is simply that no one has any experience on the subject, and that there is no valid reason whatever why the whole of the heat in a system should not be turned into work, as well as any part of it. Indeed, it is quite possible to conceive of a condition in which every portion of the heat contained in a gas would be turned into work. The so-called proof is not in any way a proof. I can remember when the argument used to stop at the words "combined engine"—not in Maxwell's treatise, be it observed—and then we were told that the action supposed would be contrary to the conservation of energy. Maxwell combats this notion very properly, and is driven to "contrary to experience," which is, of course not in any way a mathematical proof of an assumed mathematical law. Need I tell Mr. Cherry that a host of the first mathematicians, such as Tait, Hirn, &c., have disputed at various times and in various ways the soundness of Clausius' conclusions?

But not to unduly prolong this letter I will ask Mr. Cherry to state definitely, plainly, and without any quibble, mathematical or otherwise:—(1) In what way Carnot's theorem is to be applied to a modern heat engine, gas, oil, steam, or hot air? (2) How Carnot's theorem is to be used to prevent an engineer from making an invention, and wasting money in designing and making any particular kind of heat engine? (3) Why it is that for a given range of temperature, steam in a good engine utilises about twice as large a fraction of the heat expended as ought by Carnot's theorem to be utilised?

No doubt his reply will be that Carnot's theorem refers to a mathematical abstraction. That being so, will he kindly state, if he can, what is the use of reproducing it in text-books on thermodynamics as though it was a thing of "very great value," a "most important principle," and so on? and lastly, is it not true that I have assessed at its full value to engineers, which is equivalent to that of a treatise on the ice caps of Mars?

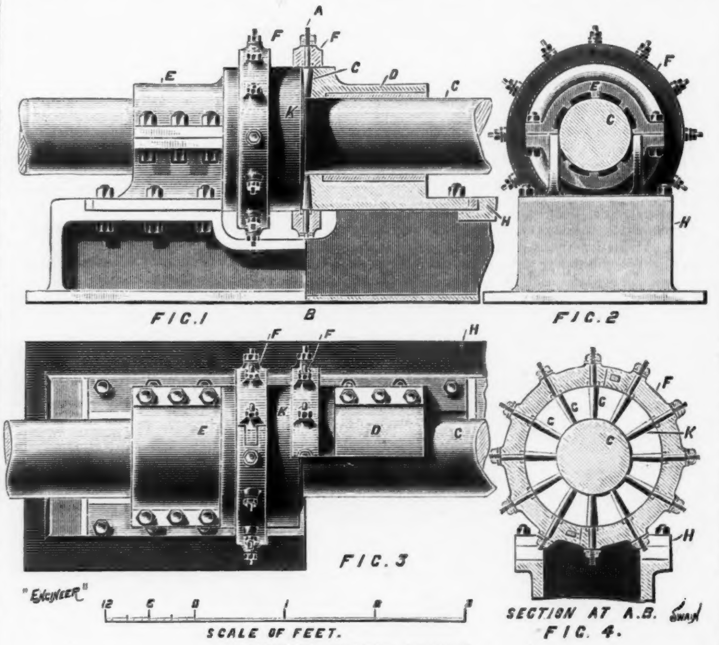
Is it too much to hope that before this discussion closes, Mr. Cherry will write one more of his oracular letters, and state plainly the case for Carnot's theorem I *should* like to see it.

December 3rd. MAURICE CROSS.

### THRUST BEARING FOR MARINE ENGINES.

SIR,—The enclosed drawing represents Pether's anti-friction thrust block to reduce the load on the engines. The principle consists in taking the thrust on a series of conical rollers carried in a ring surrounding the thrust collar on the shaft, each of which rollers revolves as the shaft rotates. The rollers are confined to a circular path by means of shoulders bearing against gun-metal bushes in the ring. This ring is also free to revolve, and thus, by the combined action of the two rotating surfaces, the load is distributed, and the speed on the thrust surfaces reduced to half that of the shaft. Tests have been made on the same thrust collar under equal loads with a model, with the result that the side having the conical rollers takes half the torsional strain to revolve as against the same thrust fitted and working against a fixed thrust box of the ordinary pattern. Referring to drawing, Fig. 1: C, shaft; D, thrust bearing in section; E, thrust bearing, outside view; F, ring retaining rollers; G, rollers taking thrust; H, foundation of thrust block; K, thrust collar. Fig. 2: C, shaft in section; E, thrust bearing; F, ring retaining rollers; H. foundation. Fig. 3: C, shaft; D, thrust bearing in section; E, thrust bearing outside view; F, ring retaining rollers; H, foundation plate; G, thrust collar. Fig. 4: C, shaft in section; F, ring retaining rollers; G G G, conical rollers; H, foundation in section; K, thrust collar. W. R. PETHER.

London, November 24th.



PETHER'S THRUST BEARING

### THE FLYING MACHINE.

SIR,—Referring to the letter on the "Flying Machine" signed "B.," which appeared in your last impression, it seems to me that the analogy of the kite is pushed much too far in dealing with a free machine, such as Mr. Maxim's would be when once clear of the rails. It is a fact well known to balloonists that when once they are up the air appears to be quite stationary relatively to them. The effect of a change in the direction of the wind in such a case is simply to make the balloon or flying machine move bodily in that direction, and there is no sideway tilting force whatever unless the body of the machine is held. This is practically the case of the kite. Just as a ship if moored broadside against a strong tide would assume a list, but if free would merely be carried bodily along on an even keel.

The time when an aërial navigator would have to be careful would be just when alighting or rising, which he should always do head to wind, as many large birds are in the habit of doing. The great disadvantage of only having a horizontal driving screw is that a level track is required to start the machine. If flying machines are to be of practical use, as I firmly believe will be the case in a very few years, they should be able to come down in any fairly level place, such as a field. This would seem to point to the use of propellers on vertical shafts, as "B." remarks, or better still, to propellers on shafts which are capable of being rotated through a right angle. At starting the shafts could be made vertical, and as the machine rose they could be gradually lowered until sufficient translational speed had been attained for the aëroplanes to take the entire weight. The whole of the power on board would then be employed in driving the machine horizontally, and this would be the minimum speed admissible to secure the maximum efficiency of the propelling apparatus. These screws on adjustable shafts would have the advantage that only one set of engines would be needed. For, if as "B." suggests, fixed auxiliary lifting screws were used, all the weight of engines necessary to drive them would be useless when once the machine was properly under weigh. This speed of maximum efficiency, if I may so term it, would probably be something over 100 miles an hour.

A far more difficult problem to tackle is the question of fore and aft stability. Any alteration of the centre of gravity, such as a man walking from one end of the machine to the other, would tend to make it either swoop or soar. A bird when he finds his centre of gravity shifted rights himself instantaneouely, and by instinct, with his tail. And it is the tail of the artificial bird which is the crucial point of the whole thing. We must either have an exceedingly practised and quick steersman, who must never let his attention wander for a moment, or better still some delicate form of mechanism, which will, on the slightest tendency of the machine to swoop or soar, immediately raise or lower the tail till equilibrium is again restored. Mr. Maxim seems to have solved the problem of mechanical flight in so far as it relates to the ability of his machine to lift its own weight, but in its present state what is to become of it when once it is up, Mr. Maxim and Providence will have to settle between them. CONTEST.

Birkenhead, November 27th.

### BOILERS AND BOILER EXPLOSIONS.

SIR,—The illustration you published in last week's issue of THE ENGINEER is by no means a solitary instance of the most woeful ignorance of some people as to their moral and legal responsibility concerning the use of steam power. I once heard of a case where the fire-box shell of an old and badly cared-for portable was roped round in two places, and wedges driven in between the plates and the ropes. This was, I suppose, considered quite a clever idea on the owner's part to keep the plates together, where the proper means seemed likely to fail. I also had a case under my own personal notice where a boiler was knowingly worked with a portion of the front plate no thicker than a sheet of paper, and when I finally prevailed on the owner to have it stopped, a hammer was driven clean through the plate by a comparatively light blow. This boiler was a Lancashire, 9ft. in diameter by 24ft. long, and was working at 60 lb. pressure. The only reply of the owner when informed of its dangerous state was, that "all he hoped was that it would hold out for a few weeks longer," and the boiler was deliberately worked in this condition for several weeks in a factory employing about 200 hands, which in my opinion was as decidedly a criminal action as that of a man who places a sleeper in front of a railway train to see if the wheel guards will throw it off.

Now, part of what I am about to say has been brought up times without number in different ways, and therefore possesses no claim to originality, but it will take no harm from a fresh thrust on the world, and that fact must stand as my apology for again bringing it up. I allude to some system of compulsory inspection. Engineers themselves, and others who are careful in a similar way, are apt, we know, to keep their plant in good order without any external pressure of any kind, simply because they realise of their own accord the economic importance of keeping that same plant in first-class—and consequently safe—repair. But it is when the first-class—to use an expression—user has considered it more beneficial to himself to part with a boiler that the real danger begins, and then a step further than inspection might well prove useful. I mean some system of compulsory registration, for as a boiler passes from hand to hand each vendor in turn expatiates on its merits to effect its sale, and thus in time all chance of obtaining any trustworthy information concerning it disappears. I would venture to say that if every boiler in the United Kingdom were inspected next week, there would be found at work hundreds that no sane engineer would ever put anywhere but on the scrap heap; and if users of boilers were to notify all particulars of changes, repairs, and general incidents that have taken place in connection with such plant, the result would be surprising, especially those reports from the agricultural districts.

The trouble is unfortunately not a lessening, but rather a growing one, for as a boiler increases in age and defects and decreases in price, so it proportionately comes more and more within the reach of persons with little or no previous experience, and who are in many ways less able to undertake the growing responsibility of its care.

What I would suggest, therefore, for older and wiser engineers to consider, is some system that would embrace the following essential points:—(1) Compulsory annual inspection by duly qualified inspectors, or carried out by firms capable of assuming the responsibility of such work, several of which are already existing. (2) Compulsory registration, to include (*a*) makers' name and date of manufacture; (*b*) past history of the boiler; (*c*) nature of past repairs, renewals, &c.; (*d*) fittings, description and condition of; (*e*) present use and pressure employed; (*f*) a yearly report, showing details of all repairs and matters of consequence connected with the boiler during the year.

It is very evident that it is neither conducive to the good of the users themselves, nor the trades or public generally, that old wasteful "tanks" should be working at pressures varying from 10 lb. to 30lb. per square inch, to the imminent danger of life and property; and it is, moreover, manifestly ridiculous and unjust that, while a firm may be indicted by a factory inspector for so small a matter as leaving a flywheel unguarded, yet others—say, for instance, a farmer, who may use an old portable in close proximity to the village street—are unmolested in the use of plant that is a far and away more dangerous matter where life is concerned.

That the difficulty would not be so very great is proved by the fact that some firms are able to register with more or less success the whereabout of their own goods. For instance, I believe the Pulsometer Engineering Company is able to refer anyone to almost any of the 14,000 of their pumps in use, and this firm will make a stipulation that place and use of a pump must be supplied before they will execute an order.

If a private firm can do this with even a small measure of success, surely it is an easy matter for an official register to be kept by making it illegal to work a boiler that is not duly entered and approved of. Of course for a few years there will be entries of a doubtful character, and many boilers of which full particulars cannot possibly be obtained, but in time as the old stagers become useless and drop out, this would correct itself, and whatever objection there may be to such a scheme there is no doubt in my mind that it would be a very desirable improvement on the present state of affairs, and it appears to be only by some such system that any embargo can be put on wilfully careless neglect.

WILLIAM F. RICHMOND.

1, Martello-terrace, Strand, Bray,
Co. Wicklow, November 4th.

Sir,—Being subscribers to your paper, we beg to report the explosion of a Cornish boiler in this village, particulars of which might be of interest. The boiler in question was used for supplying steam to drive the engine of a flour mill situated within one minute's walk from this station.

The back end plate was blown outwards, and twisted outwards like two curl papers, and lies at some distance behind the remains of the boiler-house, apparently demolishing the brick shaft in its path. The boiler itself, of which the shell and front plate are quite intact, was forced through the front of the boiler-house, across a roadway, through a brick wall and up a garden slope of considerable gradient, striking the side of a brick dwelling-house with considerable force. The tube has collapsed from end to end.

From a casual inspection we have been unable to form any firm opinion of the cause of the explosion; the engine driver tells us he had about 40 lb. pressure of steam and plenty of water in his guage glass; and, as far as we can see, all the damaged plates are of ample thickness, and the lead plug is not melted out.

SQUIER AND HINNELL,

Stanford-le-Hope, Essex, December 1st, 1894.

### MINE EXPLOSION RELIEF FUNDS.

Sir,—A correspondent, signing himself "William Brace," presumes to correct your statements in reference to the terms on which the distribution is being made of the funds subscribed for the sufferers by the Albion Colliery disaster. Your correspondent is singularly ill-informed as regards the facts, or he is guilty of serious misrepresentation. The circumstances which brought the South Wales and Monmouthshire Provident Fund into question may be set forth succinctly—but not, I am afraid, very briefly.

When the explosion took place it was estimated that a sum of between £60,000 and £70,000 would be required to succour and sustain the 135 widows and 350 children bereft of their breadwinners. You were right in saying that the Provident Society, to which the Albion colliers were contributors, had a reserve fund of £144,614. But the society had on its books—as standing obligations—the names of 750 widows and 1500 children, the sufferers from former mining disasters, of which the victims were also subscribers to the Provident Fund. If I remember rightly, you pointed out that besides the £15,000 and odd disbursed last year to widows and orphans on the books, the society had to provide for 20,000 cases of disablement, which created a casualty pension list for the time being of £21,558 per annum.

It was obviously impossible that the society, or any society constituted on similarly loose basis, could meet, out of its own resources, the sudden and exceptional drain. That, Sir, was the point which was addressed to the public in every one of the appeals I have seen. It was said in connection with the Mansion House subscription, and so with the local collections, that the moneys would be directed to the central fund, except in such cases as those in which the subscribers specifically desired that their gifts should pass directly to the widows and orphans in the Albion Colliery village.

Mr. Brace's contention would appear to be that the whole of the amount derived from public benevolence should be devoted to the benefit—an extra benefit—of the widows and orphans. I take it upon myself to say that if Mr. Brace's view had been carried out, and the Provident Society had meanwhile been required to go on paying the stipulated allowances to the widows and children, the Provident Society would have been bankrupt in a year, its resources exhausted, and all its beneficiaries—its 750 widows and 1500 children, and its 20,000 pensioners on account of mining casualties—left to find relief at other doors, and in many cases at the doors of the poorhouse.

What has been done is to constitute a Trust, in close alliance, no doubt, with the Provident Society's Executive, which will be responsible for all the sums that made up the public contribution. The Trust will reinforce the funds of the Provident Society, and avail itself of that society's machinery for the sake of economy in administration. But the society, by arrangement with the Trust, will use the public moneys, so far as may be, to give an addition to the stipulated allowances of the widows and orphans of the unfortunate Albion men. In your kindly way you described this arrangement as a compromise. I, Sir, would have preferred to say that it was a concession. Whatever this transaction may be called, it is based on the Llanerch agreement, and how far the provisions of that agreement confirm or disprove Mr. Brace's allegations, your readers may judge for themselves from an abstract taken from the only daily newspaper in South Wales which has ventured to suggest that the funds of the bountiful public have been diverted to channels for which they were not intended.

The Llanerch arrangement gives the childless widow from the Trust Fund 2s. per week, in addition to the prescribed 5s. per week she should receive from the Provident Fund. A widow with six children receives for herself 5s. 6d. per week—the 5s. coming from the society—and 2s. 6d. per week for each of her children, making a total of £1 0s. 6d. A widow with two children will receive by the arrangement 5s. per week from the society, supplemented by 2s. from the auxiliary Trust, and 1s. 6d. per week for each child. It is not much, truly, but then, as you very cogently pointed out, if a larger allowance is to be made sure of by the widows and orphans in these sad emergencies, the provident societies must be entirely remodelled and placed upon the foundation of actuarial calculations and a larger individual subscription.

AN ALBION RELIEF FUND SUBSCRIBER.

Cardiff, December 3rd.

### AMERICAN WOOD-WORKING MACHINERY AND ENGLISH MANUFACTURING INTERESTS.

Sir,—The mighty advance in wood-working machinery in the United States has evoked surprise everywhere. In America the idea is to make everything of wood without hand-labour, automatically where possible. This desire has been so successful that it is a rare exception a factory is found employing hand-work. Every known description of wood-work out of every kind of wood is made entirely by machinery. Many of these machines are veritable wonders, performing their work with a readiness and an accuracy that excites the most profound attention. Some of the English experts say of them, that they are the best examples of ingenuity ever produced, but of a lighter construction than the English make; but one must bear in mind that American iron when cast into form is very much tougher, and hence does not require so much of it to give their machines strength and solidity. This is hardly true of English iron, and in consequence thereof their machines contain a great deal more weight in iron, and consequently look more massive, but by experience it is proved conclusively that the later improved American machines are just as strong and just as capable in durability as those made by the English makers.

Progressive English manufacturers, and there are a few of them, are gradually awakening up to the fact that if they want to hold their own in the commerce of the world, they will be compelled through necessity to employ the later and far more economical methods to produce their manufactures. To do this they will have to turn to the Americans, much as it may be against their inclination.

American furniture made entirely with machinery is now getting foot-hold in England, and attracts the admiration of English buyers, not only for the beautiful designs and finish, but for superb construction, and lastly at a moderate price. Other articles of wood for domestic, vehicle, agricultural, building uses, &c., are fast creeping in, to the disadvantage of the English manufacturer. Indeed, wherein the American manufacturers succeeds it is only through the use of machinery, and therefore the Englishman, in order to protect himself from encroachment, must adopt the American idea by using American machinery, for is it not a fact that the Englishman is behind the times in the getting up of "up to date" wood working machinery? If this statement is not correct show us the fallacy of it. Machinery saves time and labour, consequently money.

J. T. B.

Cincinati, November 22, 1894.

### A PROBLEM IN VIBRATION.

Sir,—In offering the following formula for calculating the rate of vibration of "McHinery's" apparatus, I may remark that it is merely a modification of the well-known formula

$$\text{Time of vibration} = \pi \times \sqrt{\frac{\text{moment of inertia} \times \text{angular displacement.}}{\text{righting moment.}}}$$

Which applies to a body vibrating about a fixed axis, and subject to the condition that the righting moment varies directly with the angular displacement from a position of rest. For such cases the fundamental formula is exact, and the rate of vibration is independent of the amplitude of the swing.

In the present case these conditions are not fulfilled, for first, the apparatus does not oscillate about a fixed axis—with the result that the moment of inertia is greater as the inclination increases; second, the righting moment varies with the line of the angle of inclination instead of directly with the angle.

But, like a common pendulum, the apparatus approximates to the ideal case more and more as the amplitude of the swing is reduced, and therefore the formula may be expected to give fairly correct results under such conditions. It will be seen that the moment of inertia is split up into two parts, one due to the mass of the cardboard and the other to the mass of the rod. The latter is easily calculated, as it may be taken without appreciable error to have a radius of gyration measured to its geometrical centre, but the moment of inertia of the cardboard—which will be the same for all positions of the rod—is best deduced from experiment.* The formula for time of vibration in seconds is:—

$$T = \pi \times \sqrt{\frac{M R^2 + m r^2}{W d}}$$

where M is the mass of the cardboard, or weight in pounds divided by 32·2; and R is its radius of gyration in feet; *m* is the mass of the rod; and *r* is its radius of gyration. W is the weight of the apparatus in pounds; *d* is the distance of its centre of gravity from the vertex in feet. Note, both R and *r* are measured from the base. For number of vibrations per minute the formula may be written,

$$N = \sqrt{\frac{365\ W d}{M R^2 + m r^2}}$$

I find that, in order to make the result of this formula agree with McHinery's last experiment, I must give the cardboard a moment of inertia—reckoning in the above units—of ·0044, corresponding to a radius of gyration of 8in. The vibrations per minute in the three cases given then come out 81, 138, and 209, against experiment 84, 130, and 210. But considering the nature of the apparatus, one could hardly expect much better.

December 1st. A. N. SOMERSCALES.

### L.C.C. CONTRACTORS *v.* L.C.C. WORKS DEPARTMENT.—A CHALLENGE.

Sir,—We have to-day written the chairman of the London County Council as per copy below. The matter being of great importance to the ratepayers of London, we shall feel obliged if you will publish same.

REED, BLIGHT, AND Co., Ld.,
per JOHN REED, Managing Director.

London, November 28th.

[COPY.]

Albany-buildings, 47, Victoria-street,
Westminster, S.W., November 28th, 1894.

Sir John Hutton,
Chairman of the London County Council,
Spring-gardens, London, S.W.

Sir,—Our attention has been drawn to some remarks made by Mr. John Burns at a special meeting of the London County Council on Thursday last. Mr. Burns is reported to have said that although the estimates of the Works Department of the L.C.C. had been exceeded in many instances, the Council had the satisfaction of knowing that the works executed by their Works Department were of a better quality than the works executed by the contractors under the old conditions.

The excess of the estimates we do not propose to discuss, but we consider Mr. Burns' statement as to the quality of the work not only misleading to the ratepayers of London, but absolutely devoid of foundation, and calculated to damage ourselves and other contractors. We challenge proof of this statement, and would suggest that a committee of experts be at once appointed by the Council to verify it in fairness to the contractors and ratepayers of London.

We give as specimens of the works executed by us the following:—The Private Lunatic Asylum at Claybury, Dynamo House and Electric Light Station at Claybury, foundations for the Artisans Dwellings at Yabsley-street, Poplar, and the Artisans' Dwellings known as Beachcroft-buildings, Brook-street, Limehouse, E.

If in the opinion of the suggested committee of experts, these works are not equal in quality of material and workmanship to works of a similar nature executed by the Works Department of the L.C.C, we are willing to hand over £50 to any hospital you may name.

We presume that—if you adopt our suggestion—the report of the said committee will be published, and as we consider the matter of great public interest, we are sending a copy of this letter to the Press.

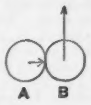
We are, Sir,
Your obedient servants,
(signed) REED, BLIGHT, and Co., Ld.,
per John Reed, Managing Director.

### THE KINETIC THEORY OF GASES: TIME OCCUPIED BY AN IMPACT.

Sir,—I was much gratified by the flattering reference to my last letter on this subject contained in your interesting article on "The Uncertainties of Science." I must, however, disclaim any intention of throwing discredit on the kinetic theory. My letter was simply written to show that "enormous velocities"—or anything approaching to them—were physically impossible in real permanent gases, and that consequently the theory required modification in that respect; and I briefly indicated at the end of the letter the nature of the modification which appeared to me to meet the difficulty, viz., "dissociation." I hope at some future time to discuss this suggested modification at a little greater length, but must refrain from doing so at present as the subject of my present letter—viz., the time of an impact—will occupy as much space as I have the conscience to ask for.

In considering the probable time of impact of molecules of real gases, which may, and probably do possess a vibratory motion, and not a motion of translation only, the time of direct impact may reasonably be supposed to depend upon the time of a vibration, which may be constant for all amplitudes. Under such conditions the time of direct impact will be the same for all velocities, the amplitude of the vibration only varying with the energy of the impact. But in the mathematical conception of a gas composed of smooth elastic non-vibrating spheres, the time of a direct impact, as will be shown hereafter, will vary inversely with the velocity of impact. To prevent misconception, I may mention that throughout this letter the word "molecule" is intended to apply to real gases, and not to include in its meaning non-vibrating smooth elastic spheres.

Although a direct impact between molecules may always occupy the same time, it does not follow that a glancing impact will do so. For suppose two molecules A and B of the same gas to be in the act of colliding, their paths being at right angles to each other as shown in the figure. In this case if a collision was an absolutely instantaneous phenomenon, A would be brought to rest, and B would move on with the combined energy of the two before impact. But if the time of direct impact is a constant definite quantity, *i.e.*, if the time of compression and restitution is always the same, then B's velocity may be so great that it will have moved beyond the influence of A before the completion of the above-named action. Under these conditions the force of restitution may not have had time to come into action at all, and even the compressive action of the impact may be reduced, until it almost vanishes, by giving a sufficiently great velocity to B. For the compression must be gradual in its action on an elastic body, it cannot act with full force at first contact like St. Venan's bars. From these considerations it follows, that the effect of a collision between two molecules depends (1) on the time of compression and restitution; (2) on the direction of the velocities of the molecules at impact, and (3) on the relative velocities of the molecules.



It has been assumed that for molecules of the same gas, the time of compression and restitution is always the same; but it would not be right to assume that in different gases the times were equal. For example, it is not difficult to show that the duration of direct impact between oxygen molecules must be four times as great as the time of impact between molecules of hydrogen. This follows from the fact that while the mean velocity of hydrogen is only four times as great as that of oxygen, the molecules of the latter gas are sixteen times the mass of the former. And since the mean pressure is the same in the two cases, it must act four times as long on an oxygen as on a hydrogen molecule. Hence it is easily seen that, when a direct collision occurs between a molecule of oxygen and one of hydrogen, they will separate before the former molecule is fully compressed.

We will now pass on to find the time of direct impact between two non-vibrating elastic spheres, or what comes to the same thing, the time of impact between a sphere and a fixed plane. Let $\bar{u}$ be the velocity of mean square of a great number of elastic spheres, resolved in a direction to one of the containing planes $l^2$. Let $p$ equal the pressure on that plane due to the impact of any single sphere impinging against it with the above velocity. Let $m$ equal the mass and $d$ the diameter of each sphere, and $n$ the number of spheres in contact with the plane at any instant. Also let $t$ equal half the time of a direct impact and $\rho$ the density of the medium. Now let $l^2$, the area of the plane, be taken so great that the number of spheres in contact with it at any instant is equal to the number in unit volume. Then $l^2 d = 1$ or $l^2 = \frac{1}{d}$.

Now the mean pressure of a sphere, during impact, on the plane impinging with the above velocity is given by the equation

$$p = \frac{m \bar{u}}{t\ l^2}.$$

Hence the pressure of $n$ spheres will be,

$$n p = \frac{n m \bar{u}}{t\ l^2}.$$

But as $n$ is the number of spheres in unit volume $n m = \rho$ the density; and as before seen $l^2 = \frac{1}{d}$. Substituting these values in the above equation and remembering that $2t$ is the time of impact = T, suppose, we get

$$T = \frac{2 \rho \bar{u} d}{n p} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1)$$

Let P equal the pressure on unit surface of the plane, then $n p = P \times l^2 = \frac{P}{d}$. Hence

$$T = \frac{2 \rho \bar{u} d^2}{P} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

If in (2) we substitute the value usually given for P—viz., $\frac{1}{3} \rho \bar{v}^2$; where $\bar{v}^2$ is the mean square of the velocity without regard to direction, and is equal to $3 \bar{u}^2$ it becomes

$$T = \frac{2 d^2}{\bar{u}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3)$$

This expression gives the time of an impact for a velocity $\bar{u}$ and for spheres of diameter $d$. The form of the expression shows that the time varies directly with the diameter, and inversely with the velocity of direct impact. The first inference we have drawn agrees with the result obtained in the first part of this letter for the difference in time of impact occupied by molecules of different gases, and the latter might perhaps have been arrived at by ordinary dynamical reasoning. When T become indefinitely small, vanishes, in fact, $\bar{u}$ becomes infinitely great, and when $\bar{u}$ vanishes T becomes infinitely great, which latter result is obvious without any mathematical reasoning.

If Dr. Watson is correct in considering that the mathematical conception of a collision is that of an absolutely instantaneous phenomenon—"Kinetic Theory of Gases," note to page 1—then it would appear from the above equation that all the velocities would be infinite,* and the Maxwellian distribution of velocities would have no meaning. If on the other hand the time of impact varies, as it must, then when the velocity of impact between two spheres is exceedingly slow, their impact may occupy an appreciable time compared with the average time of free path. So that in this case the probabilities of the collision between them being completed before impact with a third commenced would be very small indeed. This seems somewhat antagonistic to Dr. Watson's proof of the Maxwellian distribution—"Kinetic Theory," note to page 1—but it must be conceded that the probability of an impact between two spheres with very low velocities may, according to the conditions of the problem, be very slight indeed, but it seems to me that these conditions require to be definitely laid down.

In the proof given for equation (3), the value of the pressure on unit surface in terms of the mean square velocity is given as $P = \frac{1}{3} \rho \bar{v}^2$. In giving this value a concession is made to the present accepted opinion; but I have given ample reasons in former letters to show that the correct value of P is $\frac{1}{6} \rho \bar{v}^2$, and with this latter value equation (3) becomes

$$T = \frac{4 d^2}{\bar{u}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

As the value of P in terms of $\bar{v}$ and $\rho$ is of great importance in the kinetic theory—so important indeed that with the value $\frac{1}{6} \rho \bar{v}^2$ I was able to show in a former letter—May 4th, 1894, page 370—that the ratio of specific heat could be directly found from it, for permanent gases, when the density and pressure at a given temperature is known. I should like to give a further short proof of the correctness of the above expression.

Suppose a stream of inelastic particles to impinge directly against a plane, then the pressure against the plane will be in proportion to the density of the stream and to the square of the velocity. Now suppose a stream of elastic particles to be reflected backward and forwards between two planes, my contention is that the pressure will still be in proportion to the density and not to

---

* If the number of vibrations of the cardboard when unloaded is observed and found to be, let us say, 140 per minute,

$$\text{the moment of inertia} = \frac{365\ W d}{N^2}$$

$$\text{,,} \quad \text{,,} \quad = \frac{365 \times {\cdot}312 \times {\cdot}865}{140 \times 140}$$

$$\text{,,} \quad \text{,,} \quad = {\cdot}005.$$

Or, if a position is found for the rod, which does not alter the rate of vibration, then the distance from that position to the base, is the radius of gyration of the cardboard alone.

* Comparatively few of the velocities might be zero.

half the density of the stream. For consider a single particle, it of course can exercise no pressure on the plane until impact, it is then compressed by its own inertia, and it is only when this compression is completed that the centre of gravity of the particle is brought to rest. The force of restitution then comes into play, and the centre of gravity of the particle commences its journey in the opposite direction; but the particle will remain in contact with the plane, and press against it until it has regained its normal shape. Thus each particle will in turn press against the plane at either end at the end of one journey and the beginning of the next. Consequently the pressure on either plane is proportional to the density and not to half the density. This proves the proposition, but a more vigorous proof was given in my letter of April 13th last, and further developed and amended in my letter of July 27th.

Lord Kelvin estimates the diameter of a molecule as between $\frac{1}{50000000}$ and $\frac{1}{10000000000}$ of a centimetre. Taking the first of these values, the time of direct impact of elastic spheres impinging with velocities of 180,000 cm. would be $0{\cdot}44 \times 10^{-19}$ seconds; the second value would make the time of impact $0{\cdot}11 \times 10^{-23}$ for the same velocity. These times are calculated from equation 3; if equation 4 is employed, these times must be multiplied by two. The distance that a free sphere would move in the time of an impact can be obtained from the formula $s = \frac{2\,d^2\,v}{u}$ or $s = \frac{4\,d^2\,v}{u}$, according as to whether it is derived from equation 3 or 4, $s$ being the distance, and $v$ the velocity of the sphere. And if $v = u$, the expressions become respectively $s = 2\,d^2$ and $s = 4\,d^2$. Thus, it is at once seen that in a glancing impact, as in the figure, if both the spheres are moving with the above velocity, B would not move through an appreciable distance during the impact. The above remarks apply only to imaginary elastic spheres, and not to molecules of real gases. C. E. Basevi.

8, Norfolk-square, W., November 28th.

### THE PROGRESS OF NAVAL CONTRACTS.

Sir,—We notice in your issue of 30th ult. an interesting article on the Progress of Naval Contracts in private yards, but the facts do not bear out the statement that the Clyde builders have outstripped our firm in the matter of rapid construction and delivery. The order for the Banshee, Contest, and Dragon was placed with us in the middle of February last, and the first was launched on the 17th ultimo, the second on the 1st inst., and the third is to be launched on the 15th inst., the hull and fittings being as far advanced as they can be until the machinery is put on board.

The principal parts of the machinery have been placed in the Banshee, and she will be ready for steam at moorings in about a fortnight, and for preliminary trials under weigh in a few weeks after. The respective machinery for the other boats is also ready to go on board.

The orders for the Destroyers building on the Clyde were, we believe, placed during November, 1893—about three months earlier than our boats, and although the progress made with them is excellent, it will be found that merely the preliminary trials have been made, and that some time must elapse before the official trials are completed, and the boats ready for delivery. The battleship Mars progresses rapidly, and the weight of material worked into the hull and passed over scale is 3420 tons in 155 days from the laying of the keel. No doubt building in a dry dock gives us an important advantage and facility for building such a ship.

Birkenhead, December 4th. Laird Bros.

## THE VARIOUS TYPES OF BASIC OPEN HEARTH STEEL FURNACES.

The following is a report of the discussion which took place at the meeting of the Cleveland Institution of Engineers at Middlesbrough, on Mr. Bernard Dawson's paper on "The Various Types of Basic Open Hearth Steel Furnaces."

In opening the discussion, the President said that Mr. Dawson had given a great deal of time and attention to the subject, and appeared to have got people in all parts of the world to give him the latest information. The President then read communications from Mr. E. H. Saniter, Wigan; Mr. William Hawdon, ex-President; and Mr. Thomas Turner, Stoke-on-Trent.

Mr. Hawdon in his remarks said the question raised by Mr. Dawson of making steel by the Siemens basic furnace as opposed to the acid was a most important one to the Cleveland district, and would be solved by the matter of cost. He gave figures to show the small progress that had been made in basic steel manufacturing. The statistics were as under :—

| | 1880. Tons. | | 1893. Tons. |
|---|---|---|---|
| Ore raised in the United Kingdom .. .. .. .. | 18,026,000 | .. | 11,203,000 |
| Ore raised in Cleveland .. .. .. .. .. .. .. | 6,441,000 | .. | 4,625,000 |
| Percentage of imported ore in total consumption. | 12·74 | .. | 26·6 |
| Ore imported .. .. .. .. .. .. .. .. .. .. | 2,634,000 | .. | 4,065,000 |
| Cleveland iron made .. .. .. .. .. .. .. .. | 1,991,000 | .. | 1,388 000 |
| Hematite, &c., made in North of England .. .. | 519,000 | .. | 1,336,000 |
| Bessemer hematite steel ingots, United Kingdom | 1,042,000 | .. | 1,493,000 |
| Bessemer hematite steel ingots, North-East Coast | 144,000 | .. | 373,700 |
| Bessemer basic steel, United Kingdom .. .. .. | 10,000 | .. | 262 362 |
| Open-hearth steel, United Kingdom .. .. .. | 251,000 | .. | 1,456 323 |
| Open-hearth steel, North-East Coast .. .. .. | 3,200 | .. | 482.120 |
| Basic steel, United Kingdom .. .. .. .. .. | *nil* | .. | 78,645 |

The figures showed that on the north-east coast the quantity of steel ingots made in 1893 was :—Bessemer hematite, 373,700 tons; open-hearth hematite, 482,120 tons; Bessemer basic, about 160,000 tons; and Siemens basic, none; total, 1,015,820 tons. In other words, only 15·70 per cent. was basic. The loss to this country, and the Cleveland district in particular, by this importation of foreign ore was very great. If native ore were used there would be gain in the employment of men engaged in (1) the locomotives and railways in conveying the ores from the mines to the furnaces; (2) in building locomotives, wagons, &c., making rails, &c.; (3) raising coal for locomotives. On the other hand, when importing ores, men were employed (1) on the ships carrying the ore; (2) raising coal for these ships; (3) in building the ships and engines, rolling the plates, &c.; (4) in loading and unloading the vessels. Of course with native ore more men would be engaged at the local mines. The balance of gain would doubtless be in favour of native ore, but it was not so much so as appeared at first sight. That there was an advantage in the Bessemer basic process was certain, and it was to be hoped that the experiments going on with the Siemens basic might prove equally satisfactory.

Mr. Thomas Turner's communication stated that he had lately seen plants which had been designed by Mr. Dawson which had done excellent work. Ironmasters located among phosphoric ores were strongly urged to adopt the basic open-hearth process and utilise those ores. That for Cleveland was a wise recommendation. There was no difficulty in making basic open-hearth steel uniform and of a reliable quality. Its cost in Cleveland should be much less than acid steel, and for the industries in the North of England it was admirably adapted. Pig iron with phosphorus up to 4 per cent. could readily be worked provided silicon and other elements were kept right. In his own practice he had used pig with that percentage of phosphorus for a long period, and had got excellent results in work and excellent qualities of steel regularly. Working such pig produced very large slags worth 6s. to 7s. per ton of steel, and with that as an asset in calculation of cost, the process was worth the attention of northern ironmasters. The life of a furnace bottom largely depended on the skill in running. He had had dolomite furnace bottoms which had lasted over two years, turned out 798 charges and 10,500 tons of steel before renewing. Undoubtedly the basic process, with Saniter's desulphuriser and Darby's recarburiser, was the right thing for the North of England.

Mr. W. H. Penton (Dorman, Long, and Co., Britannia and West Marsh Iron and Steel Works, Middlesbrough) said they had for the past few weeks been getting steel successfully from Cleveland white iron, and they could make good reliable steel from it. The furnaces they employed were those they used for the acid process, but the bottom was made of dolomite.

Mr. C. J. Bagley (Moor Steel Works, Stockton) remarked that with regard to furnaces of large capacity, Mr. Dawson held that though they be economical in labour the large quantity of slag made was an objection. At the Moor they had 40-ton furnaces, and got thirty-five tons out regularly, and had no trouble. Large furnaces had an advantage in first cost. From six 40-ton furnaces they could get a much larger output for the same outlay as ten 20-ton furnaces. Less scrap and runners were produced. He had recently been working some of the steel made by Mr. Penton from Cleveland white iron, and found it very satisfactory; it stood more severe tests for thin plates than they had been able to get with their own acid steel. The quality was very regular. It had been made from ordinary white pig, treated by the Saniter process, and worked on a basic hearth. He thought the Lash furnace would be advantageous, seeing that they could tap off the slag from time to time.

Mr. Richard Howson (Middlesbrough) asked if the slag from the basic slag was saleable for agricultural purposes.

Mr. Penton said it was. He was not at liberty to state what they got for it, but it was enough almost to pay for the basic materials.

Mr. Jeremiah Head (Middlesbrough) considered that the paper had been given at a singularly opportune moment for the great steel makers of the North. Their trade was not in a happy condition at present, and they were on the outlook for anything that could improve their position. There was no doubt that the competition of Belgium and Germany, who had adopted the basic open-hearth process to a much larger extent than ourselves, was very seriously felt at present. It was curious that the North of England, with such large supplies of phosphoric ores, should be making steel by the acid process at all, with ores from foreign countries. In this basic process lay the most hopeful way of bringing back prosperity to the steel trade. In the United States, where he had lately been, they were progressing much in this direction. He had come in contact with the manager of the melting department at Carnegie's works at Pittsburgh, who said that four years ago all their furnaces at Homestead Works were acid lined; now they were basic. They usually got 25 tons of ingot per furnace, and they had hardly any difficulty in dealing with them. The local iron there was of a pretty high quality, and containing little phosphorus. They divided the pig into Bessemer hematite containing ·1 per cent. or less of phosphorus, and anything having more was non-Bessemer, and sold at a considerably lower price. Their policy was to buy the iron that contained a little more than 1 per cent., and use it in the basic-lined furnace. The cost of the process was 2s. 6d. more than the Bessemer, but the cheaper pig used more than made up for this. This basic steel was made into plates for the United States Navy and various shipyards. In Alabama the cheapest pig iron in the world was produced; it was 6s. or 7s. a ton cheaper than Cleveland pig. It was chiefly used for foundry purposes, and as they could sell all they could produce for that purpose, it had not been tried yet for steel making.

Mr. F. H. Marshall asked the difference between magnesite and dolomite.

Mr. C. H. Ridsdale, North-Eastern Steel Works, Middlesbrough, referring to the regret so often expressed that so little steel should be made entirely from Cleveland stone, said that was not owing to mechanical difficulties, but because of purely commercial reasons, by which every process should be judged. Even in the earlier period of the basic process the use of a large proportion of tap cinder indicated clearly that it was generally considered that from the stone to the ingot all mine pig was not commercially the most economical. That had been more than ever the case since the slag acquired a material value on account of its phosphoric acid as a manurial agent, and it was quite understood that that was an important factor in favour of which they were enabled to use the present quantity of stone. Whenever it ceased to pay to use tap, and they were thrown entirely on to the use of Cleveland stone as the source of the pig, it would be more than ever necessary to make the most of the available phosphoric acid which it contained, and in that respect—the production of a phosphoric slag of considerable manurial value—it seemed that the basic process would be placed at a disadvantage as compared with the Bessemer, on account of the necessarily greater dilution of the phosphoric acid, thus giving a greater weight of useless bodies to deal with per ton of slag. This was due partly from the fact that a large proportion of the oxygen needed was supplied in the form of ore, which though introducing a good deal of iron, also introduced objectionable impurities. Then the sandage from the pig and sand from the roof of the furnace were introduced, which would not be in the Bessemer. All these impurities in turn required extra time, which, as it also was impure, introduced in turn inert bodies. For a charge of 20 tons pig and four tons scrap, there would as a minimum in that way be introduced, together with the time necessary, about 40 cwt. of impurities more than would be the case if the same iron was converted into steel by the Bessemer process. That, on the smallest total quantity of slag that could be made, would reduce the phosphoric acid to only about 9½ per cent., as compared with 12¾ per cent., which could be obtained from the same pig by the Bessemer process. Respecting the space taken up by the slag, the specific gravity was 3·45 to 3 5, and of the ingot metal 7·85 to 7 9., the slag being two and a-quarter times the volume of the same weight of metal. These were cold, and difference when molten would be still more marked, because of the frothing of the slag. Another interesting question was as to whether white or ordinary Cleveland forge pig would be used. White pig, if a large demand for it arose, could not be made at a much lower rate than forge. It was a question whether they could produce white Cleveland containing not over 6 per cent. successfully.

Mr. J. E. Stead said it was a pertinent question to ask what the price of Cleveland white iron would be if a really good market could be found for it. He could state that basic slag from open-hearth furnaces was very remarkable, and he was continually analysing slag sold at a very good price. The phosphorus was not as great in quantity in the slag from the open-hearth basic as it was from the Bessemer basic furnaces, but the difference was not great—15 per cent. in the former, against 18 per cent. in the latter. But while they had a smaller percentage of phosphorus with the open-hearth basic slag, they got a larger quantity of slag. With respect to the Lash furnace, he thought that it would be very convenient to have the furnace on rollers, because when a large quantity of slag accumulated on the top of the metal a portion of that slag might be run off, and the process of purifying the steel would be facilitated. Then from one charge in the furnace they could get different qualities of steel, for they could run portions off at different times, and if the steel they got at any time did not suit them they could put it back into the furnace. The whole or part of the charge of a furnace could be run out just as the operator liked. Referring to the Saniter process, Mr. Dawson evidently spoke in his paper of the ladle process and not the steel. Mr. Saniter had two processes—one in which he purified the pig iron from sulphur in the ladle, and in the other he added chloride of calcium to the open-hearth furnace.

Mr. Bernard Dawson in replying, said very large furnaces had been in use—some of 40 tons and some of 70 or 80 tons, and he heard the Americans were intending to put up one of 150 tons. It was all very well working large acid furnaces, but it was different with basic furnaces, and it was better to deal with smaller masses. He could state that basic open-hearth slag was very reliable, and some steel makers had told him that the only profits they made were those they got from their slag. He knew that some of the Staffordshire firms had sold their make of slag for years to come. Much was being sent for manurial purposes to Germany from King's Lynn or other East Coast ports.

Mr. Charles Wood interpolated the remark that this basic slag manure was chiefly used by beet-root growers. The Lash tilting furnaces was ingenious; it had been used for basic steel-making. With respect to white pig iron, he did not think the supply was large, because makers did their best to avoid producing it. He did not think they would care to produce that quality continuously, say, for six months. If he were an ironmaster he would not like his furnaces to produce either mottled or white for so long; he was afraid they would not be on at the six months' end. The speaker said he had been asked to state the difference between magnesite and dolomite; but he was not prepared to do that, as there was much diversity of opinion on the subject, and there had been most fierce discussions thereupon in the German technical societies and journals. Referring to the Batho furnace, he said the great first cost was an objection, and there were comparatively few in existence. The space they took up was also against their adoption generally, and many stuck to the old Siemens type. The figures that had been given in the discussion were very useful. It was all very well importing foreign ore when this country was at peace; but the matter would assume another complexion if anything occurred to hinder our imports, and then more attention would be paid to the basic open-hearth process.

A vote of thanks was passed to Mr. Dawson for his paper.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

Considerable comment has been aroused this week in trade circles by a statement as to the condition of trade, made during the past few days by Sir Alfred Hickman, M.P., who declares that neither at the Spring Vale Furnaces nor at the steel works is a penny of profit being made. The same state of things applies to his Staffordshire colliery. He is producing nearly one-third of the total pig iron in the district, and it is declared that unless an advance in price occurs, the present condition of absolute absence of profit must continue. The outlook for trade for next year, under these circumstances, is certainly not a very bright one.

"Conditions which determine the Choice of a Steam Engine" was the title of a paper read on Saturday before the South Staffordshire Institute of Iron and Steel Managers, by Mr. John W. Hall. With engines running fairly successfully in daily practice at speeds ranging from 30 to 300 revolutions per minute, using steam varying in pressure from 20 lb. to 200 lb. per square inch, in one, two, three, or more cylinders, either condensing or non-condensing, and consuming, say, from 15 lb. of coal per horse-power per hour to one-tenth of this quantity, there is certainly a very large range of types from which to select—without mentioning such exceptional instances as the Parsons turbomotor, which runs ordinarily at about 12,000 revolutions per minute, and has been run successfully at 18,000; or the Laval steam turbine, which runs at 30,000; the Davey motor, using steam below atmospheric pressure, or the Perkins engine, employing it at 400 or more pounds per square inch above that pressure. The author gave an interesting enumeration of the various factors which go to decide the choice, and succeeded well in his attempt to assign to each its relative importance. He incidentally expressed the opinion that probably the day is very near at hand when regenerative gas furnaces will be generally used for puddling and reheating. In the discussion the weakness of many of the engines existing in the ironworks of Staffordshire was pointed out, and therefore the difficulty of practising economy by using high steam pressures. The lecturer suggested, as to one such case, that another cylinder of small size should be added, and that the steam should then be transferred from that to the existing cylinder. The strain upon the latter under the circumstances would not be much more than at present. At the same time he admitted that there was a good deal of difficulty in altering old engines.

The work of the South Staffordshire Mines Drainage Commissioners during the past month has proceeded steadily and satisfactorily. The rainfall has been 3 34in., which is again above the average. At the same time the quantity of water to be dealt with was less than in the previous month by 1380 tons per day. A pleasing instance of quick repairs in the case of an engine breakdown was afforded during the month, when the bottom rod in No. 1 plunger lift at the New Moat engine broke through the timber without any previous warning. The fracture took place close to the joint, and is attributed to the alternate action of compression and tension acting on the decayed timber. The accident occurred at an awkward time — for it happened on a Sunday night. No time was lost, however, in carrying out the emergency orders, and by the use of telephone, horses, and several messengers, the repairing staff and men for starting the auxiliary Gospel Oak engine were soon on the ground, and steam was put through the cylinders of this auxiliary within six hours of the mishap, which beats previous records by five hours. A new rod was fixed to the Moat engine and all repairs completed within fifty hours of the accident, without injury occurring to any mine in the deep.

The proofs of all kinds of barrels at the Birmingham Proof House have been :—1893, 335,271; 1892, 379,086; 1891, 361,631. This shows a decrease of 43,815 in the number passing the Proof House last year, as compared with the year previous. Not a single accident has occurred in any department during 1893. The superannuation pension scheme is still working satisfactorily. The balance-sheet for 1893 shows that the assets of the Proof House Guardians at the close of the year were estimated at £28,073, as against £28,227 in the previous year. The English gun trade continues to experience severe competition, caused by cheaper foreign labour abroad, and by protective duties upon the English goods when entering foreign markets. The stamping of foreign-made arms with the English proof marks, though conferring a guarantee of safety in use, yet operates further in conferring an imaginary English origin upon foreign goods, and this still somewhat affects home-manufactured arms in competition with them.

That machinery used in the process of gas-making is dearer than it used to be is one of the arguments being employed just now by the Gas Committee of the Birmingham Corporation to protect themselves against further demands for cheap gas. The public are, however, well satisfied with a reduction of 3d. decided upon this week, which brings the price down to 2s. 3d. or 2s. 7d., according to the scale of consumption. Birmingham is now lower than seventeen large towns.

Messrs. Kynoch and Co., of Birmingham, the well-known ammunition makers, have fixed on a site for a new cordite factory in the neighbourhood of Arklow, county Wicklow, Ireland.

The officials of the Birmingham Association of Mechanical Engineers have been appointed for the coming year. At the Association's annual meeting on Saturday, the president, Mr. E. Hazel, was unanimously re-elected. The vice-president, Mr. J. Mills; the treasurer, Mr. J. F. Crockatt; the committee, Messrs. W. Bacon, J. Burns, J. Cox, and A. W. Hayes; the auditor, Mr. J. R. Meiklejohn; and the secretary, Mr. L. O'Brien, were also re-elected.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The general position throughout the iron trade of this district continues one of dragging on through the remainder of the year, with a vague sort of anticipation of some possible improvement next spring. In the meantime the tendency of price is to get still lower, and any business that is to be secured is competed for at exceedingly low figures. With regard to the engineering industries the position continues about stationary; it does not get worse, but there is still an absence of any real improvement, and with few exceptions establishments are not only indifferently off for work, but see no present prospect of becoming busier.

The Manchester iron market on Tuesday was fairly well attended, but extreme slackness of demand was again the report all through, and except that outside brands of pig iron were firm at recent quotations, a weak tone prevailed generally as regards prices. Users of raw material continue to buy only in the smallest hand-to-mouth quantities, or where they do enter into transactions beyond this, some excessively low quotation has in most cases been the inducement. Lancashire pig iron makers who still quote nominally on the basis of about 39s. for forge to 42s. for foundry, less 2½ per cent., delivered Manchester, are practically out of this market in face of the much lower figures at which Lincolnshire can be bought, and they are only booking occasional small orders with special customers. Lincolnshire iron continues to ease down, especially as regards forge qualities, for which there is only the most limited inquiry owing to the depressed condition of the finished iron trade.

During the past week sales have been made at prices equal to about 37s. 6d. net cash, delivered Manchester, which is about 6d. under the minimum quotation of a week ago, and this price would not only now be readily taken by most makers, but there are even lower quotations in the market from merchants. Foundry qualities are fairly steady, Lincolnshire averaging about 39s. to 39s. 6d., with Derbyshire still quoted about 43s. up to 45s. net cash, delivered equal to Manchester. Middlesbrough iron, if anything, shows rather more firmness; low class ordinary brands might still be bought at 43s. 10d. net cash, delivered Manchester, but for anything like good brands 3d. to 6d. above this is quoted. For Scotch iron prices remain about 46s. 6d. to 47s. for Eglinton, and 47s. 6d. to 48s. for Glengarnock net prompt cash delivered at the Lancashire ports.

In the manufactured iron trade there is still only a very limited weight of new business coming forward, and forges are either on short time or only about two-thirds the plant is kept running. Prices gradually tend downwards, Lancashire bars being now readily obtainable at £5 5s., not only for shipment but for inland sales; North Staffordshire bars have also been quoted at £5 5s. for shipment, and only in exceptional cases average more than £5 7s. 6d. for inland sale. For Lancashire and Staffordshire sheets, £6 17s. 6d. to £7 2s. 6d. represent about the full prices for delivery here, and the Lancashire hoopmakers—at a meeting on Tuesday—decided to reduce their list rates 2s. 6d. per ton, quotations now being £5 15s. for random and £6 for special cut lengths, delivered Manchester or Liverpool. This reduction has been made not with the expectation that it will lead to any greatly increased business, but is based more upon the lower prices at which pig iron is now obtainable, and the slight reduction which has been effected in wages.

The steel trade continues extremely quiet, with little or nothing doing to really test prices. Ordinary foundry hematites nominally average about 52s., less 2½; low-class billets are readily obtainable at £3 17s. 6d. to £4, with better-class billets quoted at £4 7s. 6d. to £4 10s.; steel bars, £6 to £6 2s. 6d.; and boiler plates £6 2s. 6d. to £6 5s. delivered in the Manchester district.

In the metal market business continues very slow, with no further quotable change on list rates for manufactured goods.

I understand that one of the best-known Lancashire engineers who visited Belgium with the Iron and Steel Institute a few months back, and was then very much impressed with the development of electricity, not only for lighting, but for motive purposes, is at present making a special tour on the Continent for the purpose of further investigating electrical appliances and developments, with the view of extending the new branch of business he has recently opened out for the manufacture of electrical motors; and I may add that at his works near Manchester he has recently put up one of the most powerful and perfectly-equipped electrically driven cranes that has so far been erected in this country.

Quite a new design of gas engine, specially constructed for electric lighting work, is being introduced by Messrs. Crossley Brothers, of Openshaw, and they have at present in hand one of these new motors which they are building for the Altrincham Central Electrical Supply Station. This is a four-cylinder engine, specially designed for absolutely steady driving, and receives two impulses for every revolution. The firm are also introducing a new one horse-power nominal gas engine, the arrangement of which is similar to that of their present half horse-power engines with middle crank. In their oil engines Messrs. Crossley have introduced several important modifications and improvements since the earlier types were designed, and a considerable extension of their works has been necessary to find accommodation for this comparatively new branch of their trade. These oil engines are now made up to 14-horse power nominal, and at present Messrs. Crossley have in hand an order for two oil engines, with air-compressors combined, which are intended to work the fog signal machinery at Rattray Head, and I may add that this order, which came from the Commissioners of Northern Lighthouses, was placed with Messrs. Crossley as the result of a protracted trial of similar engines at the Pladda Lighthouse.

In connection with my recent visit to the works of Messrs. Muir and Co., referred to last week, there were one or two other interesting specialities in the way of engineering which in my previous notes I had not space to deal with. Amongst these I noticed a new countershaft arrangement which had just been fitted to one of their lathes for driving by friction with double friction pads, and ball thrust bearings, and adjustable tension spring. This, I was informed, had given very good results, and allowed the operator to get any speed or feed desired within the capacity of his machine, and was readily controlled by means of a cord at the rear. They had also just put down a new automatic bevel-wheel planing machine, of American type, which planes both ways, and had, I was informed, given great satisfaction. In their lathes, Messrs. Muir are also making a speciality of double-geared headstocks, so that they can be arranged to work single speed, or single geared, or double gear, and they had just completed for one of their special milling machines a cutter 24in. long and 5in. diameter, for milling through cranks and large marine engineering work and forgings.

The coal trade continues extremely depressed, with pits not only working short time, many of them only three to four days per week, but supplies excessive and prices barely maintained, one of the leading firms in the Manchester district having been compelled with the commencement of the month to modify their list rates both for round coal and engine fuel to meet the keen competition from other quarters. Generally, however, quotations remained unchanged, and with some increased activity in the house-fire trade, here and there attempts are being made to slightly harden up the better qualities, but with scarcely any success.

Common round coals still meet with but a very slow sale for iron-making, steam, and general manufacturing purposes, and engine classes of fuel, although, perhaps, not quite so excessive a drug as they have been recently, are still plentiful, with the result that surplus supplies are pushed upon the market at extremely low figures. At the pit mouth best Wigan Arley coals average 10s. 6d. to 11s.; Pemberton four-foot and seconds Arley, 9s. 6d. to 10s.; common house coals, 7s. up to 8s.; steam and forge coals, 6s. 6d. to 7s.; and slack from 3s. and 3s. 6d. for common to 4s. 6d. and 5s. for better qualities, with special lots of slack from outside districts offering at 1s. 6d. to 2s. per ton at the pit mouth.

In the shipping trade there is still only a very limited business doing, with steam coal delivered at the Garston Docks or the High Level, Liverpool, ranging from 8s. for inferior sorts to 8s. 6d. and 8s. 9d. for better qualities.

*Barrow.*—The hematite market is lifeless and unchanged. Orders for pig iron are quiet, and neither on home or on foreign account is much business being done. Bessemer qualities are being less sold on local account, and in forge and foundry iron very little is being done. Stocks during the week have increased 2192 tons, and now stands at 169,632 tons, being an increase since the beginning of the year of 75,009 tons. Prices are easy at 44s. to 45s. per ton, net, f.o.b., for Nos. 1, 2, and 3, and warrant iron is quoted at 43s. 4½d., net cash, sellers, and 43s. 3½d. buyers. Thirty-two furnaces are in blast, compared with thirty-three in the corresponding week of last year.

Iron ore is still greatly depressed, and orders are only few, most of them being confined to the small wants of smelters in the immediate district. Prices are unchanged.

Steel makers are, generally speaking, short of orders. The contract booked last week for 5000 tons of light rails for the Indian State Railways does not represent much work for a mill capable of turning out nearly 1000 tons a day. Other orders are scarce. Prices are steady at £3 10s. for heavy sections.

No new contracts are noted for ship plates, but the mills are busy on old orders, and will remain so well into March. In the meantime new orders are expected. Steel castings of heavy weights are in big demand. Hoops and billets are quiet in tone, and blooms, slabs, and wire rods are neglected.

Shipbuilders and engineers are very busy now on the Admiralty and general orders in hand, and a brisk winter and an active spring may be expected. No new orders are now in the market.

Coal and coke are quiet, and sales are few. Coke is still dear at 17s. per ton, delivered here from East coke ovens. Steam and shipping coal in poor request.

Shipping steel shows signs of marked depression. The exports of pig iron during the past week from West Coast ports reached 7240 tons, compared with 6809 tons in the corresponding week of last year, an increase of 431 tons. The exports of steel last week were 8562 tons, compared with 12,623 tons in the corresponding week of last year, a decrease of 4061 tons. The aggregate shipments to date this year represent 326,745 tons of pig iron and 363,767 tons of steel, compared with 258,842 and 436,959 tons in the corresponding period of last year, an increase of 671,903 tons of pig iron and a decrease of 73,192 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

SINCE my last letter more seasonable weather has prevailed in this district. Most of the fog has left us, and this has had its influence upon the house coal trade. This business has shown a decided improvement during the week. Many of the thick seam collieries, however, are making only four days. The metropolis is not taking such a large demand as was anticipated, and nothing but a protracted spell of cold weather will bring the demand up to the average. It was thought that during the winter the United States market would do a much larger trade than it has done before, but this expectation has been disappointed. The productive capacity of the district is now greater than ever. Prices are very weak, and had it not been for the agreement with the men on the wages questions, remuneration would have further declined. At some collieries the men are demanding concessions in their wages, and have even threatened to strike. The owners have replied that they might set the pits down if they chose, that there was no trade, and they could afford to stand for a time. Quotations are about the same as when last reported. Silkstone coal is at 9s. to 10s. 6d. per ton, Barnsley softs 8s. 6d. to 9s. 6d., Flockton makes from 8s. to 9s., and secondary qualities from 7s. to 7s. 9d.

The steam fuel trade is only moderate for the season. The Humber ports are taking a fairly good quantity, and the railway companies maintain a steady demand mainly on contract account. The requirements for the home market are, however, only fair, and prices are weak. Barnsley hards are from 7s. 6d. to 8s. 3d. per ton; Parkgate and other qualities from 6s. 9d. to 7s. 3d. per ton. The North-Eastern Railway Company is at present seeking tenders for the supply of locomotive fuel, owing to the languid condition of which keen competition is looked for. It will be at least a fortnight before the arrangements are completed.

Gas coal is reported to be in increased request, and most contracts are now completed, or nearly so. Prices range from 7s. to 8s. per ton, and supplies are plentiful at these rates. Slack and smudge are in the same depressed state. Although the output has of late been somewhat restricted, prices do not improve. Unriddled slack fetches from 3s., and riddled 5s. per ton, in quantities. Smudge can be easily obtained at 2s. to 2s. 3d. per ton. The coke trade is in a good condition, and business holds up well. The bulk is used for smelting purposes, and prices vary from 9s. 6d. to 11s. per ton.

Many complaints are heard both in the light and heavy industries. It is certainly true that in some directions full time is not being worked, and the weight of business, except in several specialities for which there is an abnormal demand, is not equal to what was anticipated. Inquiry, however, discloses the fact that there is not, generally speaking, so much ground to grumble, although it is the case that new orders are being placed very slowly, and the expectations of improvement, which were noted at the beginning of the year, have not yet been realised. It is now almost impossible for there to be any real revival of business this year, but there are anticipations of a very good year's working to begin with the New Year. Railway material is now being manufactured in fair quantities, and the armour plate factories are fully employed on Government account. The depression in the iron market is partly attributable to the keen competition of northern firms for orders usually placed in the Sheffield district. Makers of rails, girders, &c., finding the call for these productions to be very light, have turned to Bessemer billets, which are now at quotations leaving a very narrow margin of profit. Hematites are at 50s. to 52s. per ton, delivered in Sheffield. Lincolnshire iron, 38s.; Bessemer billets, £5 7s. 6d.; bar iron, £5 5s. to £5 15s. at makers' works.

In the lighter industries business in files has been satisfactory in regard to output, which will no doubt be in excess of that of last year. Owing mainly to the keen and extraordinary competition, profits have been cut down to a lower margin than Sheffield firms have been accustomed to. Machine-made files are now being very freely used, and being turned out in large quantities in this district.

Ivory goods have been in good request for the home markets during the last few weeks, but manufacturers of these high classes of articles have had no orders from abroad worth mentioning, foreign demands having mainly been for common pearl goods, and xylonite haftings. Dealers in ivory complain bitterly that the public buy xylonite under the impression that it is ivory, and suggest that all articles made of the inferior hafting material should be marked as such.

The "boom" in the cutlery and silver plate trades, which has been reported during the last few weeks, now appears to have fallen off in many cases. There were, of course, the usual orders for Christmas and New Year, but these having been mainly completed most firms are anything but busy, more especially in the cutlery department. One section of the cutlery trade—spring-knife department—is employing its men upon full time, mainly on account of orders from America. These houses, which are supplying the United States with butchers' knives, are profiting most by the reform of the tariff, the new duties treating this class of cutlery more favourably than any other. The commercial outlook throughout the greater part of the United States is becoming brighter every week, and Sheffield may count upon still further advancing her trade with the States early in the New Year. Some very good orders have lately been received in this city from the Argentine Republic for butchers' knives, forks, and spoons. On several occasions reference has been made to the increase in the use of sterling silver goods over those of silver plate, &c., owing principally to the cheapness of silver. Not many, perhaps, are aware of the enormous extent of that increase. In spite of the fact that this tendency has been conspicuous for several years, the head of a firm, which practically monopolises the whole of the rolling for local silversmiths, states that the quantity of silver rolled during the months of October and November show an increase to the amount of one-third as compared with the corresponding period of last year. Nor is there any appreciable difference in the amount of German silver and Britannia metal, although several firms roll and cast their own metal. The conclusion come to is that the whole industry of silver and electro-plate manufacture is rapidly increasing. While few reports are heard of firms giving up this important branch, many are published of houses adding it to their cutlery business. The cheapness of silver does not seem to have had, as was anticipated, any effect upon the manufacture of electro-plated goods. Fairly well-to-do people now purchase sterling silver appointments for their tables, instead of, as before, the best electro-plate, the difference in price being so small, and yet the production of plated goods has not decreased, but increased. Owing to the cheapness of plated goods, many homes are now being furnished with these beautiful goods for the first time.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

AN unsatisfactory report cannot but be given with respect to the trade of this district. Little business is being done in any branch, and now that the winter season has practically commenced, any important improvement is not likely to be experienced until people begin to buy for spring deliveries. Certainly the prospects of business for the next two months are not comforting, but makers and merchants generally are sanguine that a revival of trade will follow in the spring. At present manufacturers have to be content if they realise the bare cost of production for their goods, but many cannot even do that, and profits to even the most favourably situated firms are almost out of the question. Though prospects for the winter are bad, yet the opinion is that prices will not be further reduced to any material extent, but if they are it will be necessary to blow out some of the furnaces. That would be a good thing even now, especially in the hematite pig iron trade, where, it is said, the output exceeds the requirements even more largely than is the case in connection with Cleveland pig iron, but the exact extent of the over-production cannot be ascertained, as no statistics relative to the stocks of hematite or basic iron are collected. The extent of the over-production in Cleveland pig iron is known; it has been 37,737 tons this year. Only in three out of the eleven months of the year has there been reported a decrease in stocks, viz., in February, March, and April, the aggregate decrease being 28,207 tons. Just over the period when a reduction of stock might have been counted upon, when what is generally the briskest part of the navigation season, there were decreases. In January the increase was 8676 tons; in May, 11,000 tons; in June, 9178; in July, 9745; in August, 13,298; in September, 5476 tons; in October, 4689; and in November, 3697 tons. It certainly is very depressing to find that in November with such large shipments—91,257 tons—there should have been any increase in stocks. Most people looked for a decrease, and if with such exports it has been found impossible to avoid an increase, what chance is there during the next three months of preventing an increase when the exports will naturally be considerably less. Stocks will be even more rapidly augmented than they have been without some steps are taken to reduce the production. It would seem very desirable that this should be done in the case of hematite iron, and it would be better for the makers and the trade generally if such a course were taken, for with a reduced production there would be some chance of arresting the fall in prices, while the lessened consumption would bring about easier prices for materials. At present the position is, that the selling price of the produce is declining, while the cost of materials is not being reduced at all. There are fourteen furnaces more in operation in the North of England than there were at this time last year, but clearly there are too many at work, in face of the winter time- and when during the last seven months, extending over the best period of the year, stocks have been increased over 56,000 tons in Cleveland pig alone.

The returns of the Cleveland Ironmasters' Association for November have proved less satisfactory than had been looked for, because people, forming their estimates on the excellent shipments that were being reported, expected to see some decrease in stocks, instead of which there was an increase of 3697 tons. The exports of hematite pig iron were little in excess of the October figures—14,210 tons, against 13,525 tons, whereas the total shipments were 11,004 tons more than in October. This reveals an unsatisfactory feature, viz., that the inland consumption of Cleveland pig iron has declined, which means greater depression in the finished iron and foundry industries; and no doubt this is so, for some of the ironmasters report that they have had instructions to keep back deliveries of some of the iron which should have been sent inland last month in accordance with contracts made. The statistics show that ninety-five furnaces were at work last month, of which fifty-one were making ordinary Cleveland iron, and forty-four hematite, &c., these figures being the same as those reported for October. Two furnaces were reported to be in course of erection at Skinningrove. These are the first that have been erected in Cleveland during the last twenty years, and only one or two have been built in the whole of the North of England; but during that interval at least twenty-four have been demolished. The production of pig iron last month was 123,658 tons of Cleveland iron—2970 tons decrease on October—and 130,194 tons of hematite, basic, and spiegel iron—5487 tons decrease; total, 253,852 tons—decrease, 8457 tons. The decrease is accounted for by there being a day less in November than in the previous month. The total amount of Cleveland pig iron in stock at November 30th was 200,571 tons—3697 tons increase. Makers had 98,678 tons unsold—2289 tons decrease; makers' stores held 3680 tons—1054 tons increase; the North-Eastern Railway Company's stores, 7000 tons—increase, 2350 tons, and Connal's stores, 91,213 tons—increase, 2582 tons. No particulars are given of the stocks of hematite iron, but Messrs. Connal and Co. say they had 76,210 tons of hematite iron in their warrant stores, or an increase during the month of 5553 tons.

The pig iron shipments from Middlesbrough reached 91,257 tons in November, the heaviest this year, 11,004 tons more than in October, and 21,269 tons more than in November last year. From the Tees the following are the quantities of the iron and steel shipped in the months named :—

| | Pig iron. | Manufactured iron. | Steel. | Total. |
|---|---|---|---|---|
| | Tons. | Tons. | Tons. | Tons. |
| November, 1894 | 91,257 | 12,877 | 22,581 | 127,085 |
| October, 1894 | 80,253 | 11,953 | 28,539 | 120,745 |
| November, 1893 | 69,988 | 12,486 | 15,054 | 97,538 |

To India 15,196 tons of iron and steel were shipped last month; to Scotland, 40,029 tons, nearly all pig iron; to Germany, 10,976 tons; to Holland, 6101 tons; to Italy, 4765 tons, all pig iron; to Belgium, 1948 tons, all pig iron; to Denmark, 5992 tons; to Russia, 3414 tons.

Quotations for Cleveland pig iron are well maintained, but for hematite iron they are easier than they were last week, thus making the situation more difficult for the latter, as they cannot get any relief in the cost of production, Rubio ore being firmly maintained at 12s. 1½d. per ton delivered in the Tees; and coke is fully 12s. 3d. per ton at the furnaces in the Middlesbrough district, prices which have ruled for a considerable time, during which hematite iron has been falling in value. The prompt f.o.b. delivery price of No. 3 Cleveland pig is 35s. 6d., and some has been sold at that for delivery over the first quarter of next year; but beyond that makers will not sell, as they expect higher prices to rule when the exports begin to increase. The warrant market has been stronger on the whole, and for the last fortnight there has been very little change from 35s. 6d. cash. No. 4 Cleveland foundry pig iron has been sold at 34s. 7½d., and grey forge at 33s. 7½d., but most makers ask 1½d. more. Hematite pig-iron prices are extremely weak, and mixed numbers can be secured at 42s. 6d., as the position is so unsatisfactory and the prospects of the steel trade unfavourable.

The manufactured iron and steel trades are dull, and producers do not speak hopefully of the likelihood of regular work during the winter. It is very few firms that can keep their establishments in full operation now, and the same may be said of ironfounders, engineers, shipbuilders, &c. At some of the shipyards not half the berths are occupied, but they appear to be better situated on the Tees than on the Tyne and Wear. Sir Raylton Dixon and Co., at Middlesbrough, have orders for eight large steamers, but there are two yards on the river entirely closed. Some of the patternmakers are complaining because they have not been set to work since their strike terminated, and want to make out that the employers have not carried out the arrangement made when the dispute was terminated. The masters, however, cannot create work for the men directly they choose to abandon their struggle. Trade is worse than it was when the strike commenced last April, and the work has not accumulated, or masters have got their patterns made out of the district. Some of the moulders whose strike ended in September have never been able to find work since.

The directors of the Weardale Lead Company report that the produce of their mines considerably increased during the last financial year, and the average price of lead was £9 9s. 7d. per ton delivered at Parkhead, or 13s. 3d. per ton less than in the previous year, when the values were exceptionally low. The quantity of ore raised was 4971 tons, of ore dressed 4827 tons, and of ore smelted 4738 tons, the yield being 3315½ tons of pig lead.

The season of the year is favourable to the house and gas coal trades, but decidedly unfavourable to the steam coal trade, which has its harvest time during the shipping season, as so large a proportion of the steam coal raised is exported. On this account the price of steam coal has dropped rapidly during the last few weeks, so that best is obtainable at 9s. per ton, f.o.b., or 2s. less than was being realised a short time ago, and small has dropped from 5s. to 3s. 9d. per ton. Locomotive coal is cheaper, and it is expected that the extensive contract of the North-Eastern Railway for next half-year's supplies will be taken at 6d. to 9d. less than the contracts that are now running. About 8s. 6d. per ton is what is now generally quoted for locomotive coal.

Mr. Charles V. Craster, of Middlesbrough, has invented a railway fog signalling apparatus which, he claims, would make it impossible for an engine-driver to run his train past when the signal is standing at danger during a fog. It would dispense with fogmen, fog signals, and detonators.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The Glasgow pig iron market has shown a little more animation on several days this week, increased quantities of warrants changing hands. Business has been done in Scotch warrants from 42s. 5½d. to 42s. 7d. cash. Cleveland warrants have been quiet at 35s. 5d. and 35s. 5½d. The business in hematite iron has been very limited in the warrant market. Cumberland hematite is quoted 43s. 5d. and Middlesbrough 42s. 2½d. cash.

The amount of the pig iron output is practically the same as a week ago, but two furnaces have been changed from hematite to ordinary iron. There are now 25 furnaces making hematite and 42 ordinary, the total of 67 comparing with 15 at this time last year, when the output was temporarily much reduced by a strike of miners. The stocks of pig iron in Glasgow warrant stores show a reduction for the week of about 500 tons.

The values of makers' special brands are fairly well maintained:—G.M.B. f.o.b. at Glasgow, No. 1, is quoted 44s. per ton; No. 3, 42s.; Monkland, No. 1, 45s.; No. 3, 42s.; Carnbroe, No. 1, 45s. 6d.; No. 3, 44s.; Clyde, No. 1, 50s. 6d.; No. 3, 47s. 6d.; Gartsherrie, No. 1. 52s.; No. 3, 47s. 6d.; Calder, No. 1, 52s.; No. 3, 48s.; Summerlee, No. 1, 53s.; No. 3, 48s.; Coltness, No. 1, 55s.; No. 3, 51s.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 47s. 6d.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 54s.; No. 3, 50s. 6d.

The demand for pig iron for shipment is fair considering the season. The quantity cleared at the various ports during the past week reached 5926 tons, compared with 3642 in the corresponding week of last year. There was despatched to China and Japan 587 tons, Italy 572, Australia 460, India 241, Germany 219, Russia 50, Holland 385, Belgium 80, Spain 72, other countries 140, and coastwise 3120, against 1945 in the same week of 1893.

The manufactured iron and steel branches continue quiet but steady. There is a fair business doing in both iron and steel, about former prices. The exports in the past week of these articles are comparatively light, embracing sewing machines worth £5449, other machinery £4872, steel goods £3490, and miscellaneous iron goods £15,798.

The coal trade has become somewhat firmer since last report. The weather has taken a colder turn, increasing the household demand, and the shipments are larger. These facts have a favour-effect upon the market. The larger shipments are the result, to some extent, of sailings that had been delayed owing to unfavourable weather. The total quantity of coals cleared at the various Scotch ports was 163,568 tons, compared with 85,805 tons in the corresponding week.

No success whatever has attended the request of the miners for an increase of wages. This is not surprising, looking at the general state of trade, and taking into account the fact that the leaders of the men were divided in opinion as to the expediency of making such a demand at this particular time.

In the course of November there were launched from the Clyde shipyards ten vessels, with a total tonnage of 18,332, compared with 16 vessels and 20,600 tons in November, 1893. The output of the past 11 months amounts to 305,331 tons, against 264,462 in the corresponding period of last year.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE result of the last audit of the Coalowners' Sliding Scale Association is the declaration of another reduction of 1½ per cent. This was published on Saturday last, and was received with a good deal of unconcern, the colliers having quite made up their minds that the falling off in the coal trade would lead to a reduction, and a larger one was no doubt expected. The change from stormy to fine seasonable weather has been attended with a good deal of activity at Cardiff, Newport, and Swansea. The coal tonnage despatched from Cardiff alone was close upon 300,000 tons. It was the subject of comment on 'Change this week that this heavy shipment did not necessarily imply a brightening up of trade, as it was principally clearing off accumulations caused by the late storms; still there is no doubt a firmer tone begins to characterise the coal trade, and between now and the Christmas season it is very likely that there will be a good deal of business. Prices mid-week, both of best and seconds, showed a tendency to advance, and were better by 3d. a ton than Saturday's prices.

Current prices on 'Change, Cardiff, mid-week, were 11s. to 11s. 6d. best; seconds, 10s. 3d. to 10s. 6d.; dry sorts, 9s. 3d. to 9s. 6d.; best Monmouthshire, 10s. 3d. to 10s. 6d.; small, 4s. 9d. to 5s. 3d. A more satisfactory condition still begins to characterise the house coal trade, and the last report was "very firm, with a steady demand." Best households at Cardiff now command 10s. 9d. to 11s.; No 3 Rhondda, 10s.; brush, 8s. 3d. to 8s. 6d.; small, 6s. 6d. to 6s. 9d.; No. 2 Rhondda, 8s. 3d. to 8s. 6d.; small, 4s. 3d. to 4s. 6d.

Coke continues firm, with no alteration in price; patent fuel, 10s. 6d. to 11s. Pitwood still commands higher than usual figures; but this is exceptional, and with the arrival of cargoes will soon right itself. I inquired of a large importer whether any benefit had accrued from the advance of prices to £1, and even 25s., and was assured not; "stocks were low." Swansea price this week is 19s. to 20s. into truck, cash thirty days. Swansea's shipment of anthracite coal last week was marked, one vessel clearing for San Francisco with 3400 tons, and 900 tons bunkers. Swansea harbour trade in all respects was good last week, showing an excess of 18,000 tons over the preceding week. In coal there was a distinct improvement; in patent fuel the shipment was 6130 tons.

The tin-plate question is still the prominent one, maintaining its position in front even of the sad loss of Lord Swansea, who was the industrial chief of the district, and by whose mental energy and remarkable activity so many branches of labour were retained in full swing. Swansea owes much to him in the coal development alone, one great track being worked under sea. Lord Swansea was buried this week with great demonstration and regret, but it is satisfactory to learn that the various establishments will be continued.

I am glad to see, too, that the Beaufort tin-plate works, Morriston, which lost its owner in Mr. D. Davies, lately, are in good able hands. Mid-week it was announced that a settlement had been brought about at the South Wales Works, Llanelly, the men accepting a reduction of 10 per cent. So far there is not any indication of united action, and some works in the Swansea and Briton Ferry districts are under notice. It was announced this week that Llwydarth tin-plate works, Maesteg, would be closed at the end of the month. It is not improbable but that various notices now out may be recalled if the men imitate the wise course taken by those of the workmen of Mr. Rogers and Mr. Bond, Llanelly.

As regards bulk there is still a good deal doing in tin-plate, and America, Liverpool, and Bristol have been during last week the destination of a large quantity of make. The total shipment of tin-plates last week was 95,330 boxes, while the quantity received from works only totalled 72,673 boxes. Stocks now stand at 253,362 boxes.

Conversing this week with a leading tin-plate manufacturer, I remarked on the quantity of tin bar that was being sent into various Welsh ports from the North, and was assured that, notwithstanding this, the Welsh steel works, and pre-eminently those of Cyfarthfa, held the palm for superiority of tin bar. The Northern works are putting in bar, he said, at 4s. per ton under the price of some of the Welsh makers, but their bar is made by the basic process, and though good enough for common plate is not for the best. Speaking to him about the situation, he said a good deal of the present condition of trade is brought about by buyers having, in view of the American tariff passing, over-bought themselves. He had no no doubt this would right itself. and Wales would be secure of a good trade in tin-plate for years. American rivalry was not going to do much yet. Such is the substance of his views, and if wage agitation can be allayed a turn for the better may be expected.

Swansea imported 636 tons of pig and 360 tons of tin bars last week.

The iron and steel trades, which are generally dull at the end of the year, show no improvement, and prices remain at their old and low points. On 'Change, Swansea, this week, Glasgow pig warrants were quoted at 42s. 6½d. Other quotations were as follows:—Middlesbrough, No. 3, 35s. 5½d., prompt. Welsh bars, £5 2s. 6d. Steel rails, heavy, £3 15s. to £3 17s. 6d.; light section, £4 7s. 6d. to £4 10s., f.o.t. Sleepers, angles, channels, &c, according to section and specification. Steel was £6 to £6 10s. Steel sheets, £6 5s. to £6 10s. Bessemer steel bars, £4; Siemens, £4 to £4 2s. 6d.

Block tin is again receding; prices, £61 15s. to £61 17s. 6d. Tin-plate quotations remain in the old groove:—Bessemer steel cokes, 10s.; Siemens, 10s. 3d. to 10s. 6d.; ternes, per double box, 28 by 20 C., 20s. to 24s.; best charcoal, 11s. 6d. to 12s. 6d.; wasters, 6d. to 1s. less than primes.

Swansea quotation for iron ore is—Tafna, 11s.; Rubio, 11s. 3d. to 12s. An investigating contemporary has discovered that Wales is now getting its supplies of iron ore from the quarter which once supplied the Romans with its best steel. Stocks of ore are now well up for the winter season, but should they fail, the hematites of the Forest of Dean may command more attention than they do at present.

A new line of steamers has been put on between Cardiff and the South Coast ports of Southampton, Plymouth, and Bristol. Four have already been placed, and it is expected others will follow, and a large coasting traffic be developed. "Dock people" at Cardiff were interested this week by the visit of the Norwegian barquentine Reform, built on novel lines. She is a four-master, but when the wind is insufficient, can be propelled by means of petroleum. The ship is provided with two tanks, sufficient for the voyage, but has no funnel, and to the ordinary eye would seem to have no other motive power than her sails.

General Hutchinson, acting under instructions from the Board of Trade, made a special inspection of the tramway extension at Newport, Mon., this week before it was opened for general traffic. The new lines run through High-street, over Newport Bridge, Clarence-place, Chepstow-road, and Church-road, and indicate, in a marked manner, the improvement and prosperity of the port. The Government inspector, who was accompanied by the Parliamentary Committee and others, expressed himself as very pleased with the thoroughly satisfactory character of the work, and this week a start will be made with traffic.

A rumour has been current during the last few days to the effect that Sir W. T. Lewis was about retiring from official life. This I have not been able to substantiate, Sir William being absent either in Scotland or on the Continent, but I do not place much faith in it. This week another rumour was discussed gravely at the Bute Docks, "That Sir William's eldest son would take the active duties of the position at the Bute Docks, Sir William retaining the superintendence." About this, seeing the enormous strain, mental and physical, upon the representative of Lord Bute, there is certainly a likelihood.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE iron and steel trades over here continue in a most unsatisfactory condition. Fresh orders are only with difficulty obtainable, very few inquiries being generally made for winter deliveries, and a slackening off in activity is consequently reported from various establishments. With regard to the Silesian iron business the best that can be said is that in most departments a fairly regular employment has been maintained, but the prices quoted are not paying. Negotiations concerning the forming of a Central German Rolling Mill Convention have led to no result, and makers are more than ever inclined to agree to reductions. Breslau dealers have found it expedient to lower the price for bars from M. 125 on M. 120 p.t.; heavy plates have been reduced from M. 140 on M. 135 p.t., thin sheets remaining firm on M. 145 p.t.

Iron trade in Austria-Hungary is in entirely the same position as during former weeks. There is a quiet, in some instances insufficient demand coming forward for all descriptions of iron, and as foreign competition is very keen at the present moment and likely to remain so for some time to come, makers and manufacturers naturally feel rather uncomfortable. Pig iron continues scarce, and producers are therefore not very anxious to sell at the low prices which competition forces them to accept. At a late tendering, Styrian forge pig, No. 1, was sold at 58·70fl. p.t.; Hungarian forge pig being offered at 45 30 p.t.

The rolling mills have been hitherto well employed, especially those producing bars and plates, while the steel works and construction shops begin to be rather hard up for new work.

In France the iron business continues to slowly improve, the majority of the iron and steel works being satisfactorily engaged, but there are also some firms which had to restrict operations on account of a general lack of fresh orders. Up to date, prices have been with firmness maintained, and the tone of confidence which has been formerly noticed still prevails in the leading branches of industry. Recently a pretty large supply of bolts and nuts has been ordered at 305f. p.t. free Algiers.

In Belgium a quiet sort of business is still done on the iron market. Pig iron continues steadily inquired for, and prices have been on the whole tolerably well maintained. A rise in quotations for iron is generally expected to take place in the new year, which is the more likely because coke is sure to advance. Luxemburg foundry pig is at present paid with 48f. p.t.; forge pig, 47f. p.t. All sorts of plates meet with a lively request, and are better paid for than most articles of manufactured iron; the basis price of 132·50f. p.t. for iron plates, and 142·50f. p.t. for steel plates, being firmly maintained. Export in iron and steel continues depressed, which is due in some measure to the wars and troubles in the East. Just now negotiations are being carried on with Japan concerning the supply of railway requirements for narrow track railways.

The reports of the Rhenish-Westphalian ironmasters show no change in the position of the various industries since last week, except that the number of unemployed has increased in some instances. Pig iron is flat and the general lack of orders has brought about an extreme weakness in quotations, so that list prices can scarcely be considered more than nominal. The demand for finished iron also remains exceedingly quiet, and the transactions noted during the past week are of small account. Business on foreign account has been *nil*, and a great number of men have been thrown out of employment lately. Bars have been reported in fair request on home account, but nothing is gained at the present quotations, and makers do not care to book orders for forward delivery, as they firmly expect a rise in quotations before long. In girders and hoops a moderate business is done; plates and sheets have also been very quiet upon the week, quotations, of course, remaining extremely low. The wire mills are, as a rule, but poorly employed; here and there a small order has been booked, which will help to keep the mills slowly going. The construction shops and iron foundries are in a poor condition; at the locomotive shops a regular activity is reported.

Concerning the total shipments of coal from the ports of the Rhein and Ruhr—Hochfeld, Duisburg, Ruhrort—statistics show that in 1893 4,917,063 t. were shipped, out of 5,125,071 t. which came to the ports. Of the last-named quantity 1,116.997 t. fall to Duisburg, 893,971 t. to Hochfeld, and 3,114,103 t. to Ruhrort. As total production of the 169 collieries in the Rhenish-Westphalian district amounted to 38,613,146 t., it appears that one-eighth of total output has been shipped from the above-named ports.

Value of French import, during the first ten months of present year, is stated to have been 3,436,450.000f., against 3,121,980,000f. for the same period in the year 1893. Value of export, on the other hand, was 2,620,051,000f. only, against 2,666,272,000f. for the first ten months in previons year.

## AMERICAN NOTES.

NEW YORK, Nov. 28th, 1894.

REPORTS by wire from all large interior commercial centres show a steady volume of business is being transacted, and that stocks of material and merchandise are low. The opinion is entertained in commercial and manufacturing circles that the hesitating policy of consumers will disappear early next year; and that, under a more liberal provision of requirements, a slight improvement in selling prices will result. Steel mills are generally on full time. Iron rolling mills are not so crowded. Structural and plate mills will have large winter contracts placed in January. Railway companies are now ready to order increased rolling stock. General machinery is in somewhat better demand. The anthracite coal output is one million tons per week. Connelsville coke output last week, 105,720 tons. The industrial condition is slowly improving.

## LAUNCHES AND TRIAL TRIPS.

On the 27th ult. the s.s. Newlyn was sent to sea from the Tyne on her trial trip and afterwards proceeded on her first voyage to Constantinople. The vessel was built to the order of Messrs. J. J. and C. M. Forster for the Newcastle Steam Shipping Company by Messrs. C. S. Swan and Hunter, Wallsend, and engined by the Wallsend Slipway and Engineering Company. Wallsend. The Newlyn is 322ft. in length, 41ft. beam, and 23ft. 1½in. moulded depth; to carry 4400 tons deadweight. She is built on the improved awning deck type, classed 100 A1 at Lloyd's and built under special survey. The engines are 23in., 38in., and 61in. by 39in. stroke. The Newlyn is the fourth steamer built for Messrs. J. J. and C. M. Forster by Messrs. C. S. Swan and Hunter.

There was also launched last week, from the yard of Messrs. Swan and Hunter, a screw steamer built to the order of Mr. H. W. Dillon, of London, for the Dowgate Steamship Company, Limited, to augment their line of steamers, this being the second vessel built for this company by Messrs. C. S. Swan and Hunter. Length of the vessel, 336ft. over all; extreme breadth, 41ft.; depth, moulded, 27ft. 1½in. She is built on the improved spar deck grade, with poop, long bridge house amidships, and topgallant forecastle, cellular double bottom throughout, and all modern appliances for rapid loading and discharging of cargo. The vessel will be classed 100 A1 at Lloyd's, built under special survey. The engines are by the North-Eastern Marine Engineering Company, Limited, with cylinders 23in., 38in., and 61in. by 39in. stroke. On leaving the ways the steamer was named the Dowgate by Miss Willis, of Whitby.

Last week Messrs. Harland and Wolff launched a large twin-screw steamer, named the Oropesa, from the south end of the Queen's Island. The new vessel is built for the Pacific Steam Navigation Company, and intended to run in that company's line of mail steamers between Liverpool and the eastern and western ports of South America. She is 420ft. in length, and 48ft. 6in. in breadth, and has a gross tonnage of about 5370. On the main deck the first-class saloon is located, which will extend the full width of the vessel, and state-room accommodation for ninety first-class passengers. There is a second-class saloon of the same width, and state-rooms for ninety-four second-class passengers. Accommodation will be provided for 440 third-class passengers, a few of whom will be placed in rooms on the main deck forward, and the remainder on the lower deck. The Oropesa will be fitted with electric light and refrigerating machinery, and will have large spaces as promenades. Two sets of triple expansion engines, each of about 1800 indicated horse-power, have been constructed by Messrs. Harland and Wolff, the propellers being of manganese bronze. Mr. Hugh Brown was present at the launch on behalf of the owners.

ENGINEERING SOCIETY, KING'S COLLEGE, LONDON.—A general meeting was held on Friday, November 30th, Mr. E. Wilson in the chair. Mr. Cobb read a paper on "Electrical Transmission of Power." The author dealt chiefly with the different systems of distribution, and several specimens of cables and conductors were shown.

THE BIRMINGHAM ASSOCIATION OF MECHANICAL ENGINEERS.—At the annual meeting of the above Association held on Saturday last, the election of officers for the ensuing year was taken after the ordinary business had been disposed of, and resulted as follows:—Mr. E. Hazel, the retiring president, was unanimously re-elected for a second term, as was also Mr. J. Mills, vice-president. Mr. J. F. Crockatt was re-elected treasurer, and the following gentlemen were elected as members of committee:—Messrs. W. Bacon, J. Burns, J. Cox, A. W. Hayes; auditor, Mr. J. R. Meeklejohn; and the secretary, Mr. L. O'Brien, was also re-elected. The remainder of the evening was devoted to social intercourse and music.

22,693. Making Croquet Balls, A. J. Altman, London.
22,694. Bicycle Support, J. Marston and J. Whitaker, London.
22,695. Cigar Boxes, S. and P. Cohen and L. Weenen, London.
22,696. Railway-signalling Apparatus, G. A. Wildsmith and J. Scaife, London.
22,697. Putting Fire-bars in Boilers, G. P. Craig, London.
22,698. Appliance for Spreading Gum, K. Schall, London.
22,699. Water Sprinklers to Protect Buildings, R. A. Taylor, Glasgow.
22,700. Accumulators, A. Lesquoy, London.
22,701. Cutters for Paste, &c., J. G. Lochlein, London.
22,702. Expanding Plug for Drain Pipes, T. Crapper, London.
22,703. Appliance for Driving Nails, J. Bonn, London.
22,704. Optical Lanterns, W. D. Askew, London.
22,705. Screw Nuts, B. Thompson, London.
22,706. Cycles, B. Thompson, London.
22,707. Automatic Nail Puller, J. E. McMurray, Illinois, U.S.A.
22,708. Boots for Horses, F. H. Wood, London.
22,709. Children's Carriage Handles, S. T. Fawcett, D. Simpson, and J. J. Simpson, London.
22,710. Producing Soap Bubbles, J. R. von Schmädel, London.
22,711. Fasteners for Flimsy Walls, C. N. Russell, London.
22,712. Lamps, T. H. Ambrose, London.
22,713. Tobacco Pipes, G. Vaudin, London.
22,714. Frog for Railway Crossings, J. C. Shipman, London.
22,715. Gloves and Pads for Cricket, A. Pullman, London.
22,716. Mounting the Saddle of Cycles, A. Mayhew, London.
22,717. Bicycles, A. Mayhew, London.
22,718. Electric Motors, A. J. Boult.—(*E. Depoux, France.*)
22,719. Revolving Fire-arms, J. F. and H. W. Latham, London.
22,720. Compound of Beef Extract, W. Robertson, London.
22,721. A New Pilot Gas Jet Burner, T. Alexander, London.
22,722. Spring Hook for Ties, Müller and Hörman, London.
22,723. Puzzle, G. E. Rennie, London.
22,724. Lead Pencil Cases, Perry and Co., Ltd., and W. Wiley, Birmingham.
22,725. Copper Fungicide, G. F. Strawson, London.
22,726. Crystallose, J. Y. Johnson.—(*F. von H. Nachfolger, Germany*)
22,727. Thrashing Machines, J. Marshall, London.
22,728. Rope Grips for Haulage, J. H. Craven, London.
22,729. Compasses, A. W. Horsbrugh and J. H. Lee, London.
22,730. Washing Board, G. C. Marks and F. W. Thomas, London.
22,731. Steam Boiler Tubes, R. W., T. S., and W. H. Lewis, London.
22,732. Collars for Horses, &c., E. H. Ludlow, London.
22,733. Steel Tubes, C. Faulkner, F. H. Lloyd, W. E. Lloyd, and W. H. Lloyd, London.
22,734. Brakes for Vehicles, J. and F. Netsch, London.
22,735. Attaching Gloves together, S. H. Crocker, London.
22,736. Bicycles, W. J. Midleton, London.
22,737. Artificial Bristles for Brushes, S. Crosse, London.
22,738. Wire-spring Mattresses, A. H. Gale, London.
22,739. Metal Bedsteads, A. H. Gale, London.
22,740. Soldering Aluminium, L. Oliven, London.
22,741. Mixing Taps, H. C. Willmott and H. Sumerling, London.
22,742. Manufacture of Carpets, F. A. Bonton, London.
22,743. Dyes, L. G. Williams and A. Turner, London.
22,744. Lamps, S. Falk and H. C. Webb, London.
22,745. Alarms for Steam Boilers, G. F. Redfern.—(*A. C. Southwell, Corsica*)
22,746. Bells for Velocipedes, C. Lohmann.—(*H. Wessner, Germany.*)
22,747. Reaping Machines, J. Hornsby and J. Innocent, London.
22,748. Solid Metal Bars, &c., A. F. E. Dupont, London.
22,749. Protecting Ships from Torpedoes, G. H. Jones, London.

*20th November*, 1894.

22,750. Raising Metal Lids from Tins, E. H. Durnford, Kent.
22,751. Attaching Pneumatic Tires to Cycles, J. Moore, Hull.
22,752. Photographic Pictures, L. A. Marion, H. Giubout, G. Bishop, F. Bishop, and J. P. Kirk, London.
22,753. Safety Automatic Carving Fork, H. T. King, Norwich.
22,754. Lamp Stoves, H. V. Rippingille, Birmingham.
22,755. Trays for Gas Stoves, H. V. Rippingille, Birmingham.
22,756. Fertilisers, T. Twynam and F. T. Barnett, Surrey.
22,757. Pneumatic Tire, H. Jackson, Stockport.
22,758. Jacquards, W. Birks, W. J. Watson, and J. Taylor, Nottingham.
22,759. Pneumatic Tires, H. Smith, Nottingham.

22,768. A New Indoor Game, G. P. Blagdon, Birmingham.
22,769. A String Raiser, E. A. Davis and A. B. Willway, Bristol.
22,770. Electrically Illuminated Timepiece, G. Ashford, Newport.
22,771. Boots for Golfing, L. S. Stroyan, Derby.
22,772. Socket in Earthenware Pipes, J. J. Green and W. Oates, Halifax.
22,773. Forming Joints in Earthenware Pipes, J. J. Green and W. Oates, Halifax.
22,774. Joining Earthenware Pipes, J. J. Green and W. Oates, Halifax.
22,775. Earthenware Access Pipe, J. J. Green and W. Oates, Halifax.
22,776. Hammer for Pianofortes, J. Jones, Essex.
22,777. Polishing Mops, J. E. and H. E. Hartley, Birmingham.
22,778. Steam Generators, W. R. Austin, Stockton-on-Tees.
22,779. Phonographs, J. Oulton, Bradford.
22,780. Harness Buckles, E. Kipling and C. W. Walker, Bradford.
22,781. Exposing Chamber for Production of Lantern Slides, W. Tylar, Birmingham.
22,782. Solid Pattern Metal Dark Slides, W. Tylar, Birmingham.
22,783. Attachment for Photographic Shutters, W. Tylar, Birmingham.
22,784. Spark Arrester, W. P. Thompson.—(*A. Beeri, Germany.*)
22,785. Waterproofing of Textile Fabrics, J. B. and J. S. Fearnley, Manchester.
22,786. Driving Gears of Bicycles, &c., E. F. Carter, Birmingham.
22,787. Carriage Axles and Axle Brushes, J. Grice, Birmingham.
22,788. Metallic Diamond Clip-all, J. Aspinall, J. S. Baron, and F. G. Gunhouse, Blackburn.
22,789. Roller Racks for Blinds, F. Barker and S. Bott, London.
22,790. Locking Nuts upon Bolts, L. Lindley, Nottingham.
22,791. Cavity Sow-box for Sizing Machines, J. Gregson, Lancashire.
22,792. Manufacture of Handkerchiefs, R. W. Gribbon, Belfast.
22,793. Concrete and Composite Buildings, W. Orr, Glasgow.
22,794. Filing and Finishing Work, S. Hunter, London.
22,795. Playing Bowed Musical Instruments, J. Cocking, Sheffield.
22,796. Stoves, G. Woolliscroft and H. Garland, Cheshire.
22,797. Utilising Bosh Dirt, W. J. Langham, Birmingham.
22,798. Loom Shuttle Guards, J. Scaife, London.
22,799. Looms for Making Ladder Tapes, S. Butterworth, Manchester.
22,800. Valve Gear, J. Cockrane and W. Cameron, Barrhead, N.B.
22,801. Chains for Gearing, C. J. Chubb and R. H. Seaton, London.
22,802. Automatic Electrical Wonder, W. F. White, London.
22,803. Warming Beds, F. Taylor, London.
22,804. Training or Supporting Device, G. A. Bentley, London.
22,805. Preventing the Extraction of a Watch from the Pocket, C. Smallman, London.
22,806. Straining Device for Coffee Jugs, C. D. Sutton, London.
22,807. Combined Cash Till and Writing Desk, A. Barnett, London.
22,808. Vehicles for Advertising Purposes, A. M. Marsden, London.
22,809. Advertising on Hoardings, A. M. Marsden, London.
22,810. Mud Guards for Velocipedes, J. Fletcher, London.
22,811. Capes for Cyclists, J. Fletcher, London.
22,812. Type-writers, C. J. Wollaston, London.
22,813. Adjusting Device for Wind Motors, H. O. Plump, London.
22,814. Protector for Dress, &c., Pockets, A. Grove, London.
22,815. Ventilators and Construction of Greenhouses, T. Griffen, London.
22,816. Flushing Cisterns, W. H. Bailey, London.
22,817. Manufacture of Horseshoe Nails, E. Perkins, London.
22,818. Fastening Appliances for Belting, S. C. Davidson, London.
22,819. Lock and Block Electric Apparatus, E. Tyer, London.
22,820. Railway Fog Signal Apparatus, F. A. Rodewald, London.
22,821. Conduits for Electrical Conductors, J. Tatham, London.
22,822. Counting Apparatus, H. Heilbronner and M. Stein, London.
22,823. Velocipede Bells, J. M. Rimington and T. Shepherd, London.
22,824. Short-circuiting Device, F. N. Denison, London.
22,825. Bows for Violins, O. Möesner, London.
22,826. Treatment of Solutions of Zinc Chloride, J. Brock, A. E. Wareing, and F. Hurter, London.
22,827. Treatment of Solutions of Zinc Chloride, J. Brock, A. E. Wareing, and F. Hurter, London.
22,828. Utilisation of Zinc Blende, J. Brock, A. E. Wareing, and F. Hurter, London
22,829. Breaking Steel Rails, T. W. Ward and H. W. Lash, London.
22,830. Coin-freed Apparatus, R. T. and J. G. Glover, London.
22,831. Table for Use of Artists, B. Littler, London.
22,832. Door Slides, W. C. Tanner, London.
22,833. Determining Position of Vessels at Sea, D. J. Jenkins and S. Carey, London.
22,834. Vitrified Material, La Société Anonyme des Manufactures des Glaces et Produits Chimiques de St. Gobain, Chauny et Cirey, London.
22,835. Type-writing Machines, T. H. Stackhouse, London.
22,836. Adapting Fire-arms for use with Miniature Ammunition, J. F. Latnam and J. T. Musgrave, London.
22,837. Mean Pressure Indicator, A. H. Allen, London.
22,838. Advertising, A. Lucien, London.
22,839. Attaching Address Cards to Barrels, F. G. Thorne, London.
22,840. Supporting Bicycles, &c., R. W. Smith, Birmingham.
22,841. Parts of Velocipede Frames, R. W. Smith, Birmingham.
22,842. Automatic Circuit Breakers, J. Lorwa and P. Feys, London.

*26th November*, 1894.

22,843. Teapot and Slop Basin, F. W. Bentall, London.
22,844. Concentrating Sulphuric Acid, I. Levinstein, Manchester.
22,845. Power Sheep-shears, W. H. and T. Burman, Birmingham.
22,846. Spring Bedstead Frames, C. P. Robins, Birmingham.
22,847. Jacks Employed in Lasting Boots, J. M., J., A. J. and S. A. Gimson, Leicester.
22,848. Cigar-holder Plug, J. Nicholl and T. G. Dickinson, Halifax.
22,849. Stockings, H. Gregory and F. Smith, Manchester.
22,850. Adjustable Cross-bar, J. F. Braidwood, London.
22,851. Construction of Pneumatic Tires, A. Maltby, London.
22,852. Hand Starting Gear for Gas Engines, T. H. Armstrong, Northumberland.
22,853. Utilising Acid Sulphates, J. W. Walker, Glasgow.
22,854. Tea Making, W. G. M. Ivy and The Princess Company, London.
22,855. Automatic Locking-arrangement, B. Mack, London.
22,856. Varying Electrical Currents, H. C. Haycraft, London.
22,857. Application to Cops, J. Finlayson, jun., London.
22,858. New Ornamentation for Gloves, J. Hall, Leek.
22,859. Ratchet for Window-blind Cord, J. C. Pickard, Burnley.
22,860. Broach for Holding Tickets, J. F. R. Wood, London.
22,861. Hanging Window Sashes, J. G. Crowe and G. J. Cording, London.
22,862. Manufacturing Nitric Acid, W. Garroway, Glasgow.
22,863. Recovery of Coal Dust, D. Young, Glasgow.
22,864. Sieve for Cleansing Milk, R. Badger, Clitheroe.
22,865. Ventilated Lamp Reflector, W. O. Rogers, London.
22,866. Regulating Lever-action, F. E. Morriss, Norfolk.
22,867. Fusible Plug, S. O. Pearson, Manchester.
22,868. Cycle Stands, G. Lund, Bradford.
22,869. Chestnut Roaster, T. H. Douthat, Hounslow.
22,870. Tires for Cycles, J., J. Cutlan and R. Hochfeld, London.
22,871. Manufacture of Scroll Irons, J. Brockhouse, Birmingham.
22,872. Artificial Spinning Baits, R. F. Juckes, Wales.

22,873. Removing Grains from Mash Tuns, H. H. Hawkins, Manchester.
22,874. Fog-signal Apparatus, B. Buckley, Manchester.
22,875. An Inflated Sole, G. Fox, York.
22,876. Inhaler, J. G. Hewson, Manchester.
22,877. Rain Boots or Leggings, E. A. Bailey, Liverpool.
22,878. Metallic Packing, J. Inglis and J. Herdman, Leith.
22,879. Stone Saw, G. Rushworth and J. Rushworth, London.
22,880. Electric Arc Lamp, R. M. Trille, Jersey.
22,881. Brace, E. Price and E. W. Almond, London.
22 882. Brace, E. Price and E. W. Almond, London.
22,883 Measures, G. Binswanger and E. Stanley, London.
22,884. A Revolving Mast and Sail, E. B. Walker, Dorset.
22,885. Fire-doors, J. H. P. Kickhefel, London.
22 886. Attaching Uppers to Boots, T. Herbert, London.
22 887. Utilising the Flow of Tides, F. H. Kitchin, London.
22,888. Sliding Bolts for Doors, &c., J. Wharfe, London.
22,889. Lead Pipe Junctions, T., J. W., and J. H. Claughton, London.
22,890. Manipulating Electric Boxes, A. Taylor, London.
22,891. Starting Handle for Engines, A. P. Turner, Peterborough.
2,892. Boots and Shoes for Cycling, W. Gamage, London.
22,893. Gloves, F. Heafield, London.
22,894. Guns, J. Robertson, London.
22.895. Photographic Cameras, D. H. Houston, London.
22,896. Photographic Cameras, D. H. Houston, London.
22,897. Grain Separators, P. R. J. Willis.—(*H. Bailey and W. L. Gilson, United States.*)
22,898. Mortice Locks for Doors, G. J. A. Richardson, London.
22,899. Mortice Locks for Doors, G. J. A. Richardson, London.
22,900. Cauterising Apparatus, R. T. A. O'Callaghan, London.
22,901. Feed-water Heaters, R. Klostermann, London.
22,902. Making Bismuthoxyiodide-gallate, F. Lüdy, London.
22 903. Composite Sheet Metal, J. J. Atkinson, London.
22,904. Colouring Matters, J. Imray.—(*La Société Anonyme des Matières Colorantes et Produits Chimiques de St. Denis, France.*)
22,905. Vulcanisation of Caoutchouc Articles, C. E. Bergeon, London.
22,906. Machines for Cutting Rock, B. J. Atterbury, London.
22,907 Gun Boat for Coast Defence, A. Coke, London.
22 908. Water-closets, E. Chatelain, London.
22 909. Cycle Brakes, J. A. Goodby and W. Capewell, London.
22 910. Lifts, T. Mullock, London.
22,911. Letter-cards, J. E. Browne, London.
22,912. Making Cycles, A. Kriéger and R. Blondeau, London.
22.913. Displaying Advertisements, R. Haddan.—(*The Firm of G. Stollwerck, Germany*)
22,914. Fast Yellow Dyestuffs, S. Pitt.—(*L. Cassella and Co., Germany.*)
22 915. Apparatus for Stopping Ribbed Tubes, W. Boaz, London.
22,916. Mounting Grindstones, A. Clare, London.
22.917. Treatment of Ammonia, J. Brock, A. E. Wareing, and F. Hurter, London.
22,918. Electrically-heated Iron, T. B. Grant, London.
22,919. Electrically-driven Hydro-extractor, T. B. Grant, London.
22,920. An Improved Trap for Animals, G. Gibbons, London.
22,921. Trimming Type, The Linotype Company, Ld., and C. Holliwell, London.
22 922. Constructing Elastic Tires, C. H. Michelsen, London.
22,923. Advertising, M. M. Dessau, London.
22,924. Fasteners for Dresses, &c., M. Rollin, London.
22,925. Fire-proof Walls and Partitions, B. R. Ikin, London.
22,926 Packing Textile Fabrics, H. Wollheim, London.
22,927. Domestic Stoves and Ranges, J. S. Hainsworth, London.
22,928. Making Sheet-metal Cramps, H. Wollheim, London.
22,929. Artificial Ivory, E. Weihers and R. Crosse, London.

*27th November*, 1894.

22,930. Charging Pistols with Shot, B. R. Banks, Croydon.
22,931. Wrench, J. F. Whiteside, Clitheroe.
22,932. Pillow Holder and Bolster, A. L. B. McNair, Weston-super-Mare.
22,933. Check System, J. B. Edmondson and T. Lewis, Dublin.
22,934. Pneumatic Shields for Wounds, A. Cole, Dublin.
22,935. Driving Gear for Cycles, W. Ferrier, Dundee.
22,936. Steam Generator and Furnace, W. S. Bancroft, Halifax.
22 937. Securing Rail Chairs, J. J. Hayman, H. W. Pearson, and H K. Cripps, Bristol.
22 938. Heels, A. G. Brookes.—(*J. W. Brookes, United States.*)
22,939 Controlling Supply and Yarn, A. G. Brookes.—(*W. F. Draper, United States.*)
22,940. Effecting Changes of Speeds, A. G. Brookes.—(*H. H. Cummings, United States.*)
22.941. Seat-wheel and Heel Iron, J. D. Webber, Derby.
22,942. Vertical Combination Fret Cutter, J. Davis, Bradford-on-Avon.
22,943. Spinning and Twisting Yarn, W. Golding, Manchester.
22,944. Cycles, T. Pickin, Manchester.
22,945. Valves, T. Pickin, Manchester.
22,946. Gas Engines, D. Clark and F. W. Lanchester, London.
22,947. Flotation of Battleships, R. J. Plunkett, Bristol.
22,948. Lock-nuts for Bolts and Screws, L. Lindley, Nottingham.
22,949. Measuring Fluid Pressures, W. H. Watkinson, Glasgow.
22,950. Kiln, J. C. Bailey, Longport.
22,951. Printing Machines, W. H. and A. P. Dawson and J. Stott, Bradford.
22,952. Development of Photographs, A. G. Adamson, Glasgow.
22,953. Dials for Watches, J. Hawley and J. Bradley, Birmingham.
22,954. Apparatus for Cleaning Drain Traps, G. Hardie, Glasgow.
22,955. Tool-holders, T. Wallace, Barrow-in-Furness.
22,956. Umbrella Handles, B. R. Simmons and H. E. Venour, Birmingham.
22.957. Paper Bags, J. Handford, Manchester.
22,958. Rotary Engine, F. Kadlcik, F. Juppa, and J. Juppa, Glasgow.
22,959. Boilers, J. J. Bohner, Manchester.
22,960. Impromptu Class-rooms, G. Allinson and Sons, Sheffield.
22,961. Liquid for Polishing Metals, T. Blake, London.
22,962. Water-cocks, A. B. and A. C. Simmons, London.
22,963. Protecting the Joints of Windows, E. O. Read, London.
22,964. Fire-escapes, C. E. Hoefling, London.
22,965. Electric Welding, W. P. Thompson.—(*C. L. Coffin, United States.*)
22,966. Paint Compounds, W. P. Thompson.—(*W. Griscom, jun., United States*)
22,967. Winding Machines, T. Guest, T. Brookes, and M. Walsh, Manchester.
22,968. Treating Hides for Leather, W. R. Earp, Liverpool.
22,969. Treatment of Rhea Fibre, R. J. Rastrick, Hants.
22 970. Attaching Cycle Mudguards, W. and G. E. Clarke, London.
22 971. Shuttle Guards, Hartley and Ainsworth, Ld., and H. Hartley, Manchester.
22,972. Cycle Mud Shield or Protector, C. E. Vining, London.
22,973. Storage Batteries, C. S. W. Brown, London.
22 674 Door Stop and Burglar Alarm, J. W. Jones, London.
22 975. Banjo Rest Suspender, J. T. Moore, London.
22 976. Cycles, J. Mason, London.
22 977. Cranks, A. J. Boult.—(*H. Farjas, France*)
22,978. Irons for Pressing Clothes, J. W. Blackshaw, London.
22,979. Hooks and Eyes, A. Picken, London.
22,980. Fire Escapes, G. Leete and A. Young, London.
22 981. Cardboard Box Stapling Box, A. Greifenhagen, London.
22,982. Choked Drain Indicator, E. A. S. Fawcett, London.
22,983. Gas Stove and Gas Fire Burners, G. E. Wright, London.
22,984. Ceiling Brackets, J. Whitby, W. W. Slate, and J. Whitby, London.
22,985. Electric Lamp Ray Diffuser, E. Oldenbourg, London.
22,986. Portable Electric Batteries, C. J. Hubbell, London.
22,987. Furnaces of Steam Boilers, R. H. Dames, London.
22,988. Wrapping Apparatus, W. L. Wise.—(*J. P. Henderson, United States*)
22,989. Apparatus for Curing Round Shoulders, E. Wall, London.
22,990. Exhibiting Cycloramic Views, T. W. Barber, London.
22,991. Ball Valves for Cisterns, &c , J. F. Rubbins, London.
22,992. Spirit Burner for Heating Purposes, E. Lent, London.
22,993. Governing Engines, G. L. Addenbrooke.—(*R. Macdonald, Australia.*)
22,994. Correcting Manuscript Documents, M. Bartholomew, London.
22,995. Steam Boiler, A. Abrassart and P. J. Lecomte, London.
22,996. Non-explosive Reservoir for Oil, J. Bouhon, Hamburg.
22,997. Swimming Learning Apparatus, E. Edwards.—(*R. Scheller, Germany.*)
22,998. Shirt, J. Grant, London.
22 999. Furnaces, H. H. Lake.—(*E. D. Meier, United States*)
23,000. Screw Pumps, E. M. Fox.—(*W. E. Quimby, United States.*)
23,001. Water-carts, A. Riener, London.
23,002. Heating Railway Vehicles, E. H. Gold, London.
23,003. Steam Boiler and other Furnaces, B. W. May, London.
23,004. Musical Chart, H. H. Lake.—(*R. W. Lyle, United States*)
23,005. Churns, L. Sturges, London.
23,006. Process for Extraction of Gold, L. C. Daumas, London.
23,007. High-power Explosives, H. H. Lake.—(*C. S. Randall, United States.*)
23,008. Screw Propellers, J. B. Jones and J. Branson, London.
23,009. Slide Valves, E. L. Sauer and A. Coleman, London.
23,010. Lamps, S. Chandler, jun., and J. Chandler, London.
23 011. Attachments for Sinks, Drains, &c., H. Howse, London.
23,012. Electric Signalling Systems, H. E. Walter, London.
23,013. Sewing Machines, J. Morrison, London.
23,014. Presser-foot for Sewing Machines, J. Morrison, London.
23,015. Dressers for Lady Cyclists, N. A. Aubertin and A. Lebas, London.
23,016. Factory Chimneys, &c., A. H. E. Gribbohm, London.
23,017. Sleeping and Drawing-room Cars, L. F. Ruth, London.
23 018. Boring Machines, C. Cristadoro, London.
23,019. Devices for Carding Machines, A. Borios, London.
23,020. Crushing Minerals, J. C. Fell.—(*W. Hinrichs, United States.*)
23 021. Engraving Machines, C. C. Bruckner, London.
23,022. Sleep-giving, &c., Sound, P. E. Fahlberg, London.
23,023. Extinguishers for Lamps, E. Rippingille and W. Brandon, London.
23,024. Diagrams for Tacheometers, G. Gillman, London.
23,025. Can-opener, J. Bien, London.
23.026. Window Fastener, W. Shelley, London.
23,027. Locking Devices, F. J. J. Gibbons, London.
23.028. Gas and Vapour Engines, M. H. Robinson, London.
23,029. Time, &c., Indicating Device, W. Wood, London.
23 030. Elastic Handle for Velocipedes, H. J. Haddan.—(*Marcus and Co., Germany.*)
23,031. Carbonating Liquids, H. J. Haddan.—(*The Ferry Manufacturing Company, United States*)
23,032. Carbonating Liquids, H. J. Haddan.—(*The Ferry Manufacturing Company, United States.*)
23,033. Stool, E. Bolens, London.
23,034. Cyclists' Wallets, G. E. Campbell, London.
23,035. Corsets, W. Kleinwächter, London.
23,036. Rulers, H. Furmidge, London.
23,037. Cover for Culinary Purposes, S. L. Jones, London.
23,038. Box and Call Board for Hotels, J. P. Moore, London.
23,039. Elastic Stockings and Anklets, J. Lorac, London.
23,040. Windows and Cheval Glasses, R. Lanham, London.
23,041. Feeding Heaters with Water, W. Schmidt, London.
23,042. Embroidering Machines, P. Schiersand, London.
23,043. Propellers, E. Davis, London.
23,044. Draught-excluders, W. C. Tanner, London.
23,045. Pipe Cleaners, H. M. Hodges, London.
23,046. Sectional Roller for Blinds, E. T. Headech, Ashford.

*28th November*, 1894.

23,047. Stop and other Valve-chests, R. Semple, Bellshill.
26,048. Broom-fastener, W. Clode and J. Smith, Birmingham.
23,949. Steam Pumps, M. and A. Shanks and R. W. Morrice, Pollakshaws.
23,050. Metal Sheets, C. Pegram, Birmingham.
23,051. Firegrates and Stoves, E. Hallam, Derby.
23,052. Screens for Process Engraving, A. W. K. Bryan. Manchester.
23,053. Flue for Incubators, C. W. Siviter, Birmingham.
23,054. Dry Soap, H. Heaton, Bradford.
23,055. Steam Generators, C. Christmas, Birmingham.
23,056. Weaving of Textile Webbings, H. T. Ollard, Birmingham.
23,057. Candle Holder, W. Horabin, Crewe.
23 058. Harness, J. L. Bradshaw, Southport.
23,059. Device for Mixing Grain, J. L. Bradshaw, Southport.

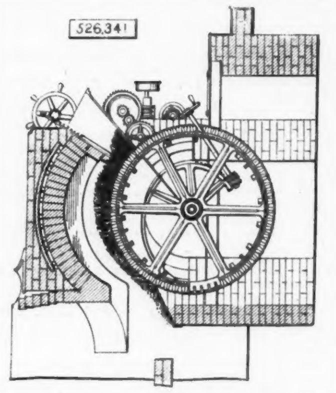
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**526,341.** Mechanical Stoker, *T. R. Butman, Chicago, Ill.—Filed January 5th*, 1894.

*Claim.*—(1) In a furnace the herein-described rotary drum-shaped grate having the end heads and the periphery formed of grate bars, said end heads having gearing and the drive shaft parallel with the grate and having the gear-wheels engaging said gearing of the heads, and means to rotate said shaft, substantially as described. (2) In a furnace, the combination with the rotary grate, of the combustion chamber above the same, having the curved arch dropped at the receiving and discharging ends, substantially as set forth, so as to contract the combustion chamber at its front and rear ends for the purpose mentioned. (3) In a furnace, the combination of a rotary grate, the combustion chamber above the same having the curved arch, the feed hopper at the front end of said chamber, and the rear discharge end of the chamber in a lower plane than the front receiving end. substantially as set forth. (4) A furnace having the rotary grate and the movable ashpan located within the grate beneath the upper surface thereof, and controlling the distribution of air through said upper surface.

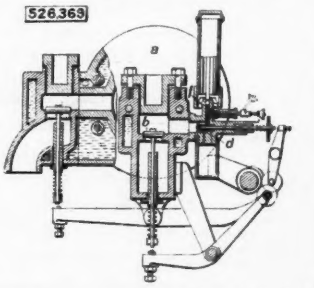
526,341



**526,369.** Gas, Oil, or Similar Motor Engine, *H. H. Andrew and A. R. Bellamy, Reddish, near Stockport, England.—Filed March* 13th, 1894.

*Claim* – (1) In combination in a gas or motor engine, the ignition tube *h*, the ignition valve, the snifting valve *k* arranged in proximity to and in communication with the ignition tube and opening at or about the same time as the ignition valve for the purpose of allowing the contents of the ignition tube to escape into the atmosphere, and a disengaging device adapted to open the snifting valve, and allow it to be closed automatically, substantially as described. (2) In a gas or oil motor engine the combination of the snifting *k* having a pivoted tumbler catch *m*; the ignition tube *h*, the ignition valve and spindle kicker plate *n* and washer *l* on the spindle of the ignition valve, all arranged and operating substantially as described and as shown.

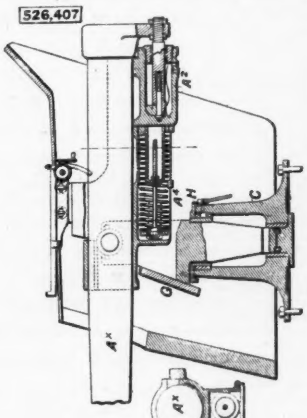
526,369



**526,407.** Quick-firing-gun Mount, *A. Noble and R. T. Brankston, England.—Filed May* 14th 1894.

*Claim.*—(1) The combination of a gun, its cradle, with trunnions supported in bearings carried by a fork at the upper end of a vertical pivot, a pedestal for the vertical pivot to rest in, a shield carried from this pivot by yielding stays and shielding a space around the front and sides of the pivot, a spring box for running out the gun carried on the under side of the cradle and open on the under side, so that the springs may be taken out and removed rearward and sights carried by an upward extension of one side of the cradle at a level above the front portion of the shield substantially as described. (2) The combination of a gun A* cradle A with its trunnions supported in bearings on a vertical spindle B, the pedestal C for vertical spindle to rest in the movable ball bearing C* at the bottom of the pedestal—recoil cylinder $A^2$ and spring box $A^3$ on under side of cradle containing a spring $A^4$ for running out the gun and open at bottom to admit of the springs being readily removed—a worm wheel H attached by friction to the pedestal—a flat shield G fixed across the front of the vertical pivot to protect the spring-box and the worm wheel, and a shield D carried from the pivot by yielding stays F to protect the space around the front and sides of the pedestal.

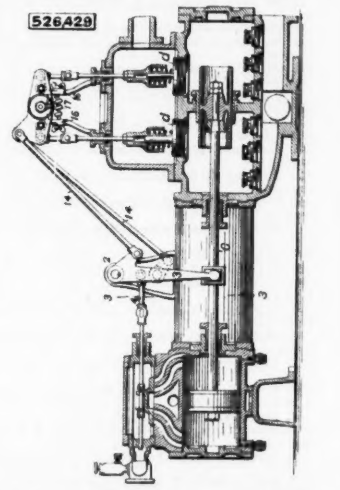
526,407



**526,429.** Valve Gear for Pumps, *C. C. Worthington, Irvington, N Y—Filed March 28th*, 1890.

*Claim.*—(1) The combination with the plunger of a direct-acting steam pump, of a valve located upon the force side of the plunger, and means substantially as described for positively closing the valve to remove the pressure of the force main from in front of the plunger as it reaches the end of its stroke. substantially as described. (2) The combination with valves *d*, of rods 10 having heads engaging said valves, oscillating lever 13, and yielding connections between said rods and lever, rock shaft 2 actuated by a moving part of the pump, and connecting-rod 14 between said shaft and lever, substantially as described. (3) The combination with the valves *d*, of rods 10 having heads engaging said valves, oscillating lever 13, bell crank levers 16 fulcrumed on said oscillating lever and connected to the rods 10, spring 17 connecting said bell crank levers, rock shaft 2 actuated by a moving part of the pump, and connecting rod 14 between said shaft and lever 13, substantially as described. (4) The combination with the valves *d*, of rods 10 having heads engaging said valves, oscillating lever 13, bell crank levers 16 fulcrumed on said oscillating lever, and connected to the rods 10, spring 17 and stops 30, rock shaft 2 actuated by a moving part of the pump, and connecting-rod 14 between said shaft and lever 13, substantially as described. (5) The combination with the piston-rods C, rock shafts 2, levers 3, and connecting-rods 4 for operating the steam valves of a duplex pump from opposite sides, of devices for closing the water valves and connecting rods 14, connecting said devices with the rock shafts 2 actuated from their own side of the pump, substantially as described. (6) The combination with the piston-rods C, rock shafts 2, levers 3 and connecting-rods 4 for operating the steam valves of a duplex pump from opposite sides, of water valves *d*, rods 10 having heads engaging said valves, oscillating levers 13 carrying said rods, and connecting-rods 14 between said levers and the rock shafts 2 actuated from their own side of the pump, substantially as described. (7) The combination with the piston-rods C, rock shafts 2, levers 3 and connecting-rods 4 for operating the steam valves of a duplex pump from opposite sides, of water valves *d*, rods 10 having heads engaging the valves, oscillating levers 13, bell crank levers 16 fulcrumed on said oscillating levers and connected to said rods 10, and spring 17, substantially as described.

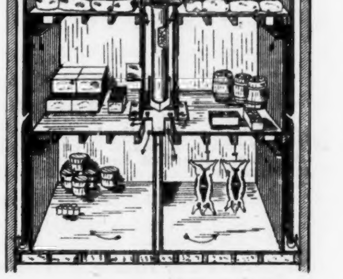
526,429



**525,695.** Cold Storage Building, *A. I. Dexter, Wauwatosa, Wis.—Filed October 23rd*, 1893.

*Claim.*—(1) In a refrigerator or cold storage building, the combination of an ice storage room; one or more produce storage rooms located below said ice storage room; downward cold air flues communicating from said ice storage room to said produce rooms; and heat intercepting flues communicating first downward and then upward from the upper parts of said produce storage rooms to said ice storage room, substantially as and for the purpose set forth. (2) The combination in a refrigerator or cold storage building of two or more produce storage rooms; a chemical refrigerator; cold air distributing flues communicating between said chemical refrigerator and said produce storage rooms; an ice storage room located above said chemical refrigerator and warm air flues, communicating from the upper part of said produce storage rooms, first downward and then upward to the upper part of said ice storage room, all substantially as and for the purpose specified.

525,695



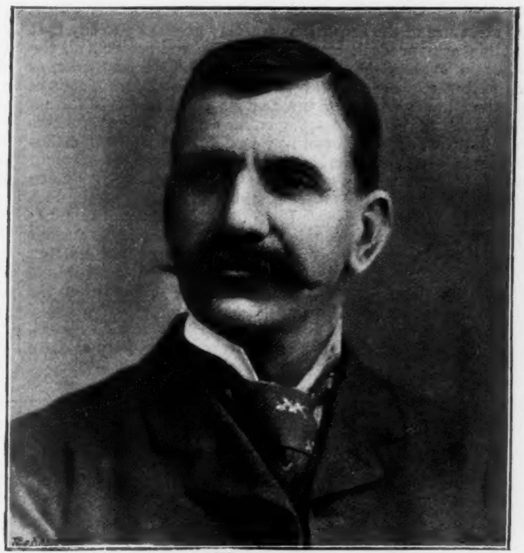
Throat Irritation and Cough.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. In contact with the glands at the moment they are excited by the act of sucking, the Glycerine in these agreeable confections becomes actively healing. Sold only in boxes, 7½d.; tins, 1s. 1½d., labelled, "James Epps and Co., Homœopathic Chemists, London."

## THE CHILIAN CRUISER BLANCO ENCALADA.

THE new Chilian cruiser Blanco Encalada, which has lately been completed at the Elswick shipyard of Messrs. Sir W. G. Armstrong, Mitchell, and Co., of Newcastle-on-Tyne, may be regarded as the latest development of the fast protected cruiser type of war vessel, and is the outcome of an experience in the design and construction of ships of this class extending over their whole history. To illustrate the growth of the protected cruiser, it is necessary to go some way back to the Comus class in the British navy, and to the Tsukushi Kan and Yung Wei built for the Japanese and Chinese Governments respectively, in 1881, at the Walker shipyard of Messrs. Armstrong. These two vessels had their coal bunkers disposed so as to afford protection to the machinery, in conjunction with slight steel protection to the engines and magazines, and in this respect they resembled the Comus class built about three years before, but they had a speed of nearly 16½ knots, against 13 in the Comus, were heavily armed, and carried a good coal supply.

From these vessels it was a great step to the Esmeralda, which was also built at Walker shipyard in 1882-3 for the Chilian Government, from the designs of Mr. George Rendel. The Esmeralda and the English cruisers of the Leander class, built about the same time, were the earliest cruisers ever fitted with a curved steel protective deck extending throughout the whole of their length. This system of protection has since been adopted so generally by our own and other Governments, not only in all the lighter and faster cruising war vessels, but in the latest and largest cruisers, such as the Edgar class, the Blake and Blenheim of 9000 tons, and now in the Powerful and Terrible of 14,200 tons displacement, and also—in conjunction with a deep armour belt—in the new armour-clads of the Majestic class. So that, whatever may be said—and there is much—in favour of outside armour protection as opposed to inside curved armour decks, the latter system, which has been adopted by the Elswick firm in all their cruisers, from the Esmeralda to the Blanco Encalada, cannot at any rate be said to have lost favour with most of our greatest authorities on naval architecture.

We append a table (p. 503) giving the principal features of some of the many cruisers designed and constructed at Elswick, in chronological order; and this table will show that Messrs. Armstrong have always more than kept on a level with all competitors in producing cruisers with powerful armaments and good protection, and in the matter of high speed they have generally led the way. To revert for a moment to the Esmeralda and the Leander class; the former had a curved steel deck of 1in. compared to 1½in. in the Leander, and she had two 10in. and six 6in. guns against the Leander's ten 6in., so that in protection the Leander, which it must be borne in mind was much the larger ship, was superior, in armament about equal, but in speed the Esmeralda went far ahead of any cruiser of the time, making 18·3 knots against 17 in the English ship. The dimensions of the two ships were as follows:—Leander, length 300ft., breadth, 46ft.; mean draught, 19ft.; displacement, 4300 tons. The Esmeralda was 270ft. long, 42ft. beam, 18½ft. draught, and 2950 tons displacement.



P. Watts

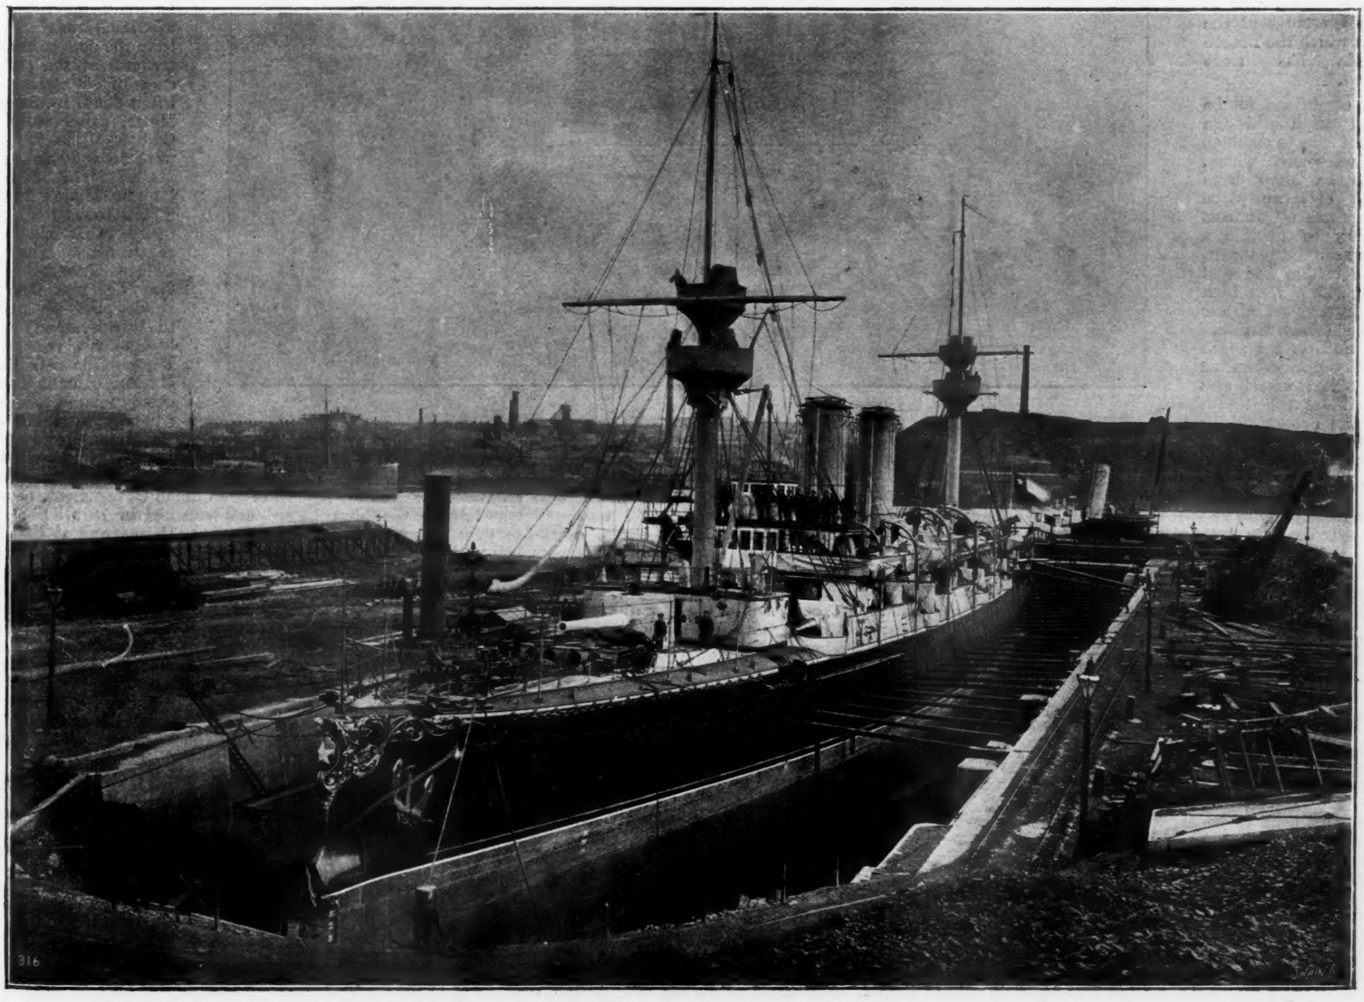


Fig. 1—THE BLANCO ENCALADA LYING IN DOCK

So successful was the Esmeralda that the Giovanni Bausan was built to the order of the Italian Government shortly after, on practically the same lines, and was succeeded by the Naniwa Kan and Takachiho Kan for the Japanese Government. These vessels were an advance upon the Esmeralda, both as regards size, protection, and speed, and were not unlike the Mersey class built for the British Navy during the same year, 1885. The Naniwa had nearly the same armament as the Esmeralda, whereas the Mersey carried two 15-ton and ten 6in. guns. In protection she was the equal of the Mersey, both ships having a curved steel deck from 2in. to 3in. in thickness; but in speed the Naniwa was superior with 18¾ knots against the Mersey's 18. The Naniwa and Takachiho were designed by Mr. W. H. White upon his joining the Elswick firm, as were also the Panther and Leopard, two small cruisers of 18½ knots speed, built at Elswick for the Austrian Government, and the Dogali for the Italian Government, which had a displacement of 2050 tons and a speed of 19½ knots.

From Mr. White's designs also, were built the two Chinese cruisers Chih Yuen and Ching Yuen, one of which is reported to have been sunk in the recent battle off the Yalu. These two Chinese vessels were an advance on their predecessors more in the direction of good defensive qualities than in speed, as they were provided with a complete armour deck 2in. thick on the horizontal, and 4in. on the sloping portions, and they carried an armament of three 8in. and two 6in., and 24 smaller quick-firing and machine guns, on a displacement of 2300 tons and a length of 250ft. Their speed was 18·5 knots.

In 1887 the small cruiser Elizabeta was launched for the Roumanian Government; she was similar in type, though rather smaller than the Blanche of our navy.

In the same year, Messrs. Thomson, of Glasgow, launched the Spanish cruiser Reina Regente. She is a very powerfully armed, well protected cruiser, carrying four 24 cm. guns, six 12 cm., and eight quick-firing, and having a deck 3in. on the flats and 4¾in. on the slopes; and at that time she was the fastest cruiser afloat, with a speed of 20¾ knots; but Messrs. Armstrong were not far behind, and in the following year the Italian cruiser Piémonté was launched at their yard. This vessel was designed by Mr. Philip Watts, who succeeded Mr. W. H. White as director of Elswick shipyard, when the latter was appointed Director of Naval Construction at the Admiralty.

Mr. Watts read a paper upon the cruiser "Piémonté," before the Institution of Naval Architects in 1889, a full account of which was given in our issue of April 26th for that year. It will, however, be interesting here to recapitulate a few particulars of this remarkable vessel, and place them side by side with the Medea class, which were built for our Navy about the same time. The Piémonté was a vessel of 2500 tons displacement, her length was 300ft., breadth 38ft., and mean draught 15ft. She carried an armament of six 6in. quick-firing guns, and six 4·7in. quick-firers and ten 6-pounders, besides smaller machine guns, and was thus remarkable as being the first war vessel armed with the new 6in. and 4·7in. quick-firing guns introduced by Elswick, and which have since formed at any rate part of the armament in almost every British war ship. Her protection consisted of a complete steel deck 1in. on the flats and 3in. on the sloping sides, and her speed with natural draught was 20½ knots, and with forced draught 22 8 knots. The Medeas were vessels of 2800 tons, 265ft. long, 41ft. broad, and 16¼ft. draught; they carried six 6in. guns, nine 6-pounders, and other small guns; they have protective decks 1in. thick on the flats and 2in. thick on the slopes, and steam at 19 knots. So that in the Piémonté was a vessel of rather less disl pacement than the Medea, with much more powerful armament, better protection, and much greater speed than her contemporary in our Navy.

The Piémonté was the forerunner of other fast cruisers designed by Mr. Watts and constructed at Elswick; but the performances of such vessels as the 25 de Mayo and the 9 de Julio, built for the Argentine Government, and the Japanese cruiser Yoshino, which made over 23 knots on her trial, and lately gave such a good account of herself in the sea fight off the Korea, are so fresh in the minds of our readers that we will only refer them to the list of vessels built at Elswick which we give, and where particulars of their leading features will be found. It is only necessary to remark here that, with the exception of the United States commerce destroyers Columbia and Minneapolis, which are much larger vessels of 7400 tons displacement, the three last-named Elswick cruisers, 25 de Mayo, 9 de Julio, and Yoshino, all surpass any similar vessels in the world in speed, and have since their departure from England given great satisfaction to the several countries to which they belong. We will, therefore, pass on at once to an account of the design and construction of the latest warship completed at Elswick, the Chilian cruiser Blanco Encalada.

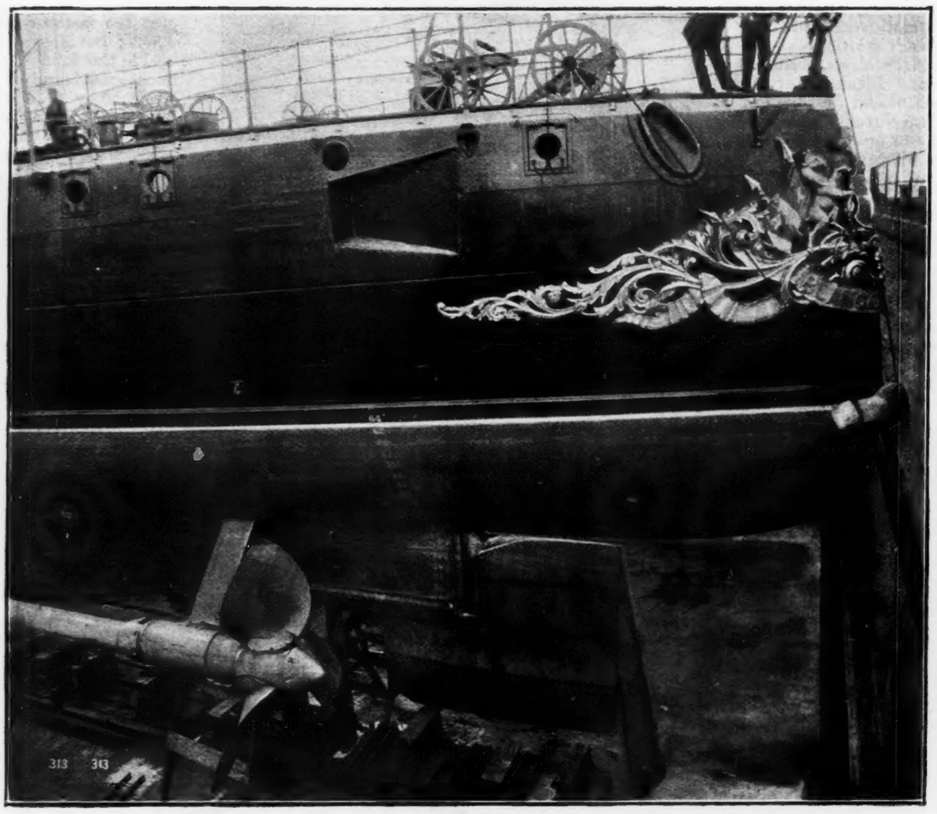

Fig. 2—STERN OF BLANCO ENCALADA IN DOCK

It must have been largely owing to the success of the various vessels described above, that the Chilian Commission appointed to obtain designs and tenders from various firms in Europe for a fast first-class cruiser, decided to accept the design submitted by the Elswick firm; this, and the fact that Sir Edward Reed was a member and technical adviser of the Commission, and that out of all the designs submitted to him by many of the best known shipbuilders in England and abroad, the tender of Messrs. Armstrong for a vessel designed by their naval architect, Mr. Watts, was finally accepted, was in itself a guarantee of the success which the Blanco Encalada has since achieved.

The conditions to be fulfilled in the design were not easy to combine in one war vessel, which, as has so often been pointed out, must be a compromise. It was necessary to provide a very powerful armament, good protection and coal supply, and a very high speed in a vessel of less than 5000 tons displacement, and on a draught of water not exceeding 18½ft. The vessel also had to be sheathed with wood and copper, which was no doubt a most valuable quality in a cruising ship for a State of South America, where docks of sufficient size to take large ships are exceedingly scarce; but which also meant more weight to be provided for in the design, and increased draught. However, the great experience gained at Elswick in vessels of the cruiser class enabled them to overcome all these difficulties, and to combine the various points asked for in a vessel of the following dimensions:—

| | Feet. |
|---|---|
| Length between perpendiculars ... ... ... | 370 |
| Breadth extreme ... ... ... ... ... ... | 46·6 |
| Draught of water forward ... ... ... ... | 17·6 |
| ,, ,, aft ... ... ... ... ... ... ... | 19·6 |
| ,, ,, mean ... ... ... ... ... ... | 18·6 |
| Displacement in tons... ... ... ... ... ... ... | 4500 |

The speed aimed at was 22½ knots, with forced draught in the stokeholds, and 20½ knots was the guaranteed speed with natural draught, both of which were exceeded on the trials, the latter by more than a knot.

The armament to be carried was two 8in. guns, ten 6in. guns, quick-firing; twelve 3-pounder Hotchkiss, ten 1-pounder Hotchkiss, and five torpedo tubes. This was an abnormally heavy armament for a cruiser of such small displacement, and if, for the two 8in. guns, two 9·2in. were substituted, the armament of the Blanco would be equal to that of H.M. first-class cruisers Blenheim and Blake, vessels of just twice her displacement.

The amount of coal to be carried on the normal mean draught of 18½ft. was 350 tons; but her bunkers, which are disposed so as to augment as much as possible her defensive qualities, are capable of holding over 900 tons of coal; and she could steam carrying this full supply at a very slightly reduced speed. With her bunkers full to start with, she could steam at a rate of 21½ knots, her full speed natural draught, for eighty-four hours and cover 1800 knots, whilst at 12 knots she could steam for twenty-eight days and traverse 8000 knots.

Her protection consists of a complete steel deck extending from stem to stern, having a thickness of 1¾in. on the horizontal portion, which is 18in. above the load water-line, and the sloping portions at the side are from 3in. to 4in. in thickness, and are carried to a depth of 4ft. 3in. below the load water-line. At the ends of the ship this deck slopes downwards, ending below water at each extremity, furnishing aft admirable protection to the steering gear and rudder head, and forward being brought down to the ram casting and securely fastened to it, greatly adding to the strength of the ram, and tending to distribute the shock of ramming over the whole of this heavy deck, and thus throughout the entire structure of the ship. It is scarcely necessary to say that this armour deck completely covers and protects all the main engines, boilers, magazines, and steering gear, as well as other spaces devoted to stores, &c., at the ends of the ship. Wherever the armour deck is cut to form a hatch or other necessary opening, armour bars or shutters are provided, which can be closed down in action; coffer-dams are also worked round all openings to a height of at least 4ft. above the water, greatly reducing the chance of water getting below, if the deck ever became flooded. In action the commander has the shelter of a conning tower built of steel armour 6in. in thickness, from which an armoured tube conveys the rods from the steering wheel situated in the conning tower, telegraphs, &c., to a position of safety below the protective deck. The guns are all protected by heavy shields, 3in. thick, in the case of the 8in. and 6in. guns. What was promised in the design has been fully realised in the ship, and for her size she is without doubt one of the most formidable cruisers afloat. The English cruisers of the Astrea class, which are also sheathed ships, have a displacement of 4360 tons, 140 tons less than the Blanco, and carry two 6in. quick-fire guns, and eight 4·7in. quick-fire guns, and eight 6-pounders, and smaller guns, and four torpedo discharging tubes. They steam at 19¾ knots, and are protected by a deck 1in. and 2in. in thickness, so that the Blanco has greatly superior armament and protection, and can steam three knots faster. The Blanco Encalada was commenced on September 30th, 1892, when the first keel plates were laid. Her framing is a combination of the transverse and longitudinal systems, and in general construction and scantlings she resembles vessels of similar type and size in her Majesty's service.

She is built with a cellular double-bottom extending throughout the space occupied by the engines and boilers, and carried on to the ends in the form of magazine and other flats. The double bottom is divided into numerous water-tight compartments, which can be utilised for water ballast, or as reserve feed tanks; and the longitudinal bulkheads to the side coal bunkers carry the inner bottom right up to the protective deck, so that with the coal bunkers above this deck, which extend over about half the length of the ship amidships, she can be said to have a double side over her whole main portion from the keel to a height of 6ft. above water. This and the subdivision of the vessel throughout into a very large number of water-tight compartments by means of transverse and longitudinal bulkheads, greatly minimises the chance of her being sunk in action. All the bulkheads below the protective deck are, where it is absolutely necessary to have communication, fitted with water-tight doors which can be closed from the main deck, and have automatic means of indicating whether they are open or shut.

In determining the lines on the model the utmost care and skill had to be exercised to obtain the best results at high speeds, and the noticeable absence of wave and eddy-making during the whole course of her trials at sea was a subject of wonder to all on board, and proved that the lines adopted left little, if anything, to be desired. Some idea of the form of the lines may be gathered from the illustration we give of her lying in dock, Fig. 1.

The powerful ram alluded to above is a great feature of the Blanco, projecting 8ft. beyond the point where the stem cuts the water-line and with its spur about 9ft. below the surface. It is made of a strong casting of phosphor bronze, as are also the stern post casting and the struts for supporting the ends of the twin propeller shafts. The rudder, which is shown in the picture of the stern of the ship in dock (Fig. 2), was, as may be seen, of a form rather unusual in such large vessels. It was first adopted at Elswick in the cruiser 9 de Julio, and proved so satisfactory that it was subsequently fitted to the Yoshino, and also to the Blanco Encalada. It is hung upon a short but very strong stern post, which is its axis, and projects below this and also in front, so that it is really a balanced rudder. The great advantage claimed for this form of rudder is that it enables a large portion of the so-called dead wood to be cut away, thus greatly reducing the lateral resistance of the vessel to turning. The admirable manœuvring qualities displayed at sea by all the Elswick cruisers have fully justified the adoption of the arrangement.

The outside plating of the Blanco was completed in June, 1893, and then the sheathing with wood was begun. This is a work that requires immense care; the danger of metallic connection, and consequent galvanic action, between the steel of the hull and the copper sheets which are finally nailed on the wood, having always to be borne in mind and guarded against. The wood used is the best teak, of a minimum thickness of 3¼in., and this is fastened to the shell with bolts of naval brass. In the region of the stem thicker plates of naval brass are substituted for the copper, where the chafe of the anchor is likely to cause great wear and tear.

The Blanco was launched on September 9th, 1893, less than a year from the date of her commencement, the performance of christening her being done by Signorita Matte, daughter of the Chilian Minister. There were also present, Senor Matte, Sir E. J. Reed, Captain Munoz Hirtado, Sir Andrew Noble, and many other ladies and gentlemen. The new Blanco Encalada glided smoothly into the Tyne amidst the cheers from the large company assembled to see the launch. We say the new Blanco Encalada, for it was decided to name this latest addition to the Chilian Navy after an old armour-clad, which, it will be remembered, was torpedoed and sunk off Caldera in the civil war in 1891. The old Blanco was, at the request of the Chilian Government, designed by Sir Edward Reed, and launched in 1875. She was a sister ship of the Almirante Cochrane, and at that time was regarded as a great advance in armour-clad construction. She had an armour belt 9in. thick, and carried six 12½-ton guns, manufactured at Elswick. She took a prominent part in the engagement of Oct. 8th, 1879, when as flagship of the Chilian squadron, she encountered the Peruvian Huascar, and which, after about an hour's fighting, was disabled by the fire of the Blanco and the Almirante Cochrane. The Blanco was sent to be repaired at Elswick shipyard in 1886. No more fitting name could therefore be found for the new Chilian ship, which was also built under the supervision of Sir Edward Reed.

After the launch the work of getting on board the machinery supplied by the well-known firm of Messrs. Humphrys, Tennant and Co., of Deptford, was quickly proceeded with. We shall describe the machinery more fully later, but it may be well to mention here that it was similar to that supplied by Messrs. Humphrys for the cruisers 25 de Mayo and 9 de Julio, which proved in every way so satisfactory. The Blanco was completed for sea with all machinery, guns, boats, and fittings on board, by July, 1894, or twenty-two months after the date of her commencement.

In a previous issue we gave an account of the gunnery trials of the Blanco Encalada, but it will not be out of place here to give a few more particulars of the armament. All the 8in. and 6in. guns are of 40 calibres length and of the latest Elswick pattern. The 8in. guns are mounted one forward on the upper deck and one aft. The after 8in. gun is shown in illustration Fig. 3, with some of the Chilian crew who came to Elswick to take the vessel away. The carriage in the front of the photograph is for mounting a 1-pounder gun for shore service.

The ten 6in. guns are mounted in sponsons on the upper deck, two capable of firing right ahead and two right astern, so that one 8in. and two 6in. can be directed right ahead or astern, and two 8in. and five 6in. can fire through an arc of at least 100 degrees on either beam, not counting the 3-pounder and 1-pounder Hotchkiss guns. Owing to the simple and handy breech mechanism of the 8in. guns, and the admirable arrangements for bringing the powder from the magazines to the guns, the 8in. as well as the 6in. may fairly claim to be called quick-firing, seeing that during the gunnery trials four rounds were fired from one of the 8in. in just over one minute, a hitherto unequalled performance in a gun of this size. The 8in. guns can penetrate 18in., and the 6in. guns 15·6in. of steel. The 3-pounder guns are placed, eight on the bulwarks and four between decks, two forward and two aft. The 1-pounders are six of them in the military tops, and four on the shelters.

Fig. 4 of the upper deck looking forward shows the breeches of some of the 6in. guns on the starboard side, and also a field carriage for a 1-pounder. It also gives a very good stern view of a second-class torpedo boat, and the derrick for lifting it. This boat, which is an unusually large and heavy one for a cruiser of the Blanco's displacement, was supplied by Messrs. White, of Cowes. A 14in. torpedo tube was fitted on board at Elswick, and provision is made for mounting a 3-pounder gun on board; in front of the field carriage is seen the steam winch, supplied by Messrs. Clarke, Chapman, and Co., of Gateshead, for working the derrick which lifts the torpedo boat; this derrick has an outreach of 48ft., and is capable of lifting 25 tons. The whole of the gear was thoroughly tested in position before the torpedo boat was itself lifted. All the other boats, including a steam launch with a speed of 8½ knots, were made at Elswick shipyard.

The five torpedo tubes, which are for discharging 18in. torpedoes, are all situated above water in three torpedo rooms; one being a fixed tube firing right forward through the stern; and four training through an angle of 60 deg., firing two on each broadside, and placed in two torpedo rooms on the lower deck before and abaft the machinery spaces. We give an illustration—Fig. 5—of one of these broadside torpedo rooms, which shows the tube and mechanism for training. On the left is a torpedo head stowed in position ready for use, and at the back is a torpedo body; and the overhead rail for transporting the torpedoes is also seen. Owing to the great length of the tubes necessary for firing these large 18in. torpedoes, they are made with a joint and hinge a little abaft the middle of each tube, to facilitate training and loading. The tubes fitted, are of the new Elswick design, and are arranged to use cordite as the impulsive agent. A series of experiments with this new arrangement have given most satisfactory results, and have proved that the velocities obtained with cordite impulse are even more uniform than those when compressed air is used. By an ingenious contrivance the pressure can be very carefully regulated, and it is found that the high velocity of over 50ft. per second is obtained with a pressure of 35 lb. in the tube; a great advantage, particularly in a bow discharge. The cordite is burned in a chamber formed in the door of the torpedo tube, and it is so arranged that it cannot be fired unless the door is properly secured, a point which has hardly received sufficient attention in the service tubes. The whole contrivance is exceedingly simple, and can be worked by any blue jacket, and there is nothing to get out of order. Other great advantages in the use of cordite are that there is no smoke or noise, air accumulators, pipes, and valves are all done away with, and there is practically no fouling of the tube. At the gunnery trials torpedoes were fired from each of the broadside tubes. Illustration Fig. 6 shows a torpedo being discharged from one of the Blanco's broadside tubes while she was lying in the Tyne off Elswick; this picture is from an instantaneous photograph taken by the photographer to the Elswick Works.

It is scarcely necessary to say that in a war vessel like the Blanco the steering apparatus is a most important feature. She is fitted with an arrangement specially designed and made at Elswick, and which has worked very well in other cruisers of similar type. Owing to the fineness of the lines aft, and to the fact that the steering gear had to be kept entirely under the protective deck, which is here brought below the load water-line, the space available for the rudder crosshead was very limited, and only just over 4ft. in width; and the rods connecting the crosshead to the tiller had to be very long, measuring 24ft., before sufficient space was found for the movement of the tiller. These rods have to pass through a water-tight bulkhead, and to allow for the lateral motion of the rods, specially designed stuffing-boxes had to be fitted which could slide on the bulkhead as the rods moved nearer or farther from the centre line of the ship in the process of steering. The tiller is fitted with a modified form of the Rapson slide, and is worked by a chain passing over two sheaves, one at each side of the ship, and round a sprocket wheel situated below, and turned directly by the steam steering engine. This engine was supplied by Messrs. Bow, McLachlan, and Co., of Paisley, and is of sufficient power to move the tiller from hard over on one side to hard over on the other—through an angle of 38 deg. each way—in thirty seconds when the ship is going at full speed. Arrangements are made, in case of emergency, for rapidly substituting hand gear for the steam gear, and *vice versâ*. The hand steering wheel is under the after shelter on the upper deck, and there are wheels in connection with the steam gear on the forward bridge, in the conning tower, and in a compartment forward in a safe position below the protective deck.

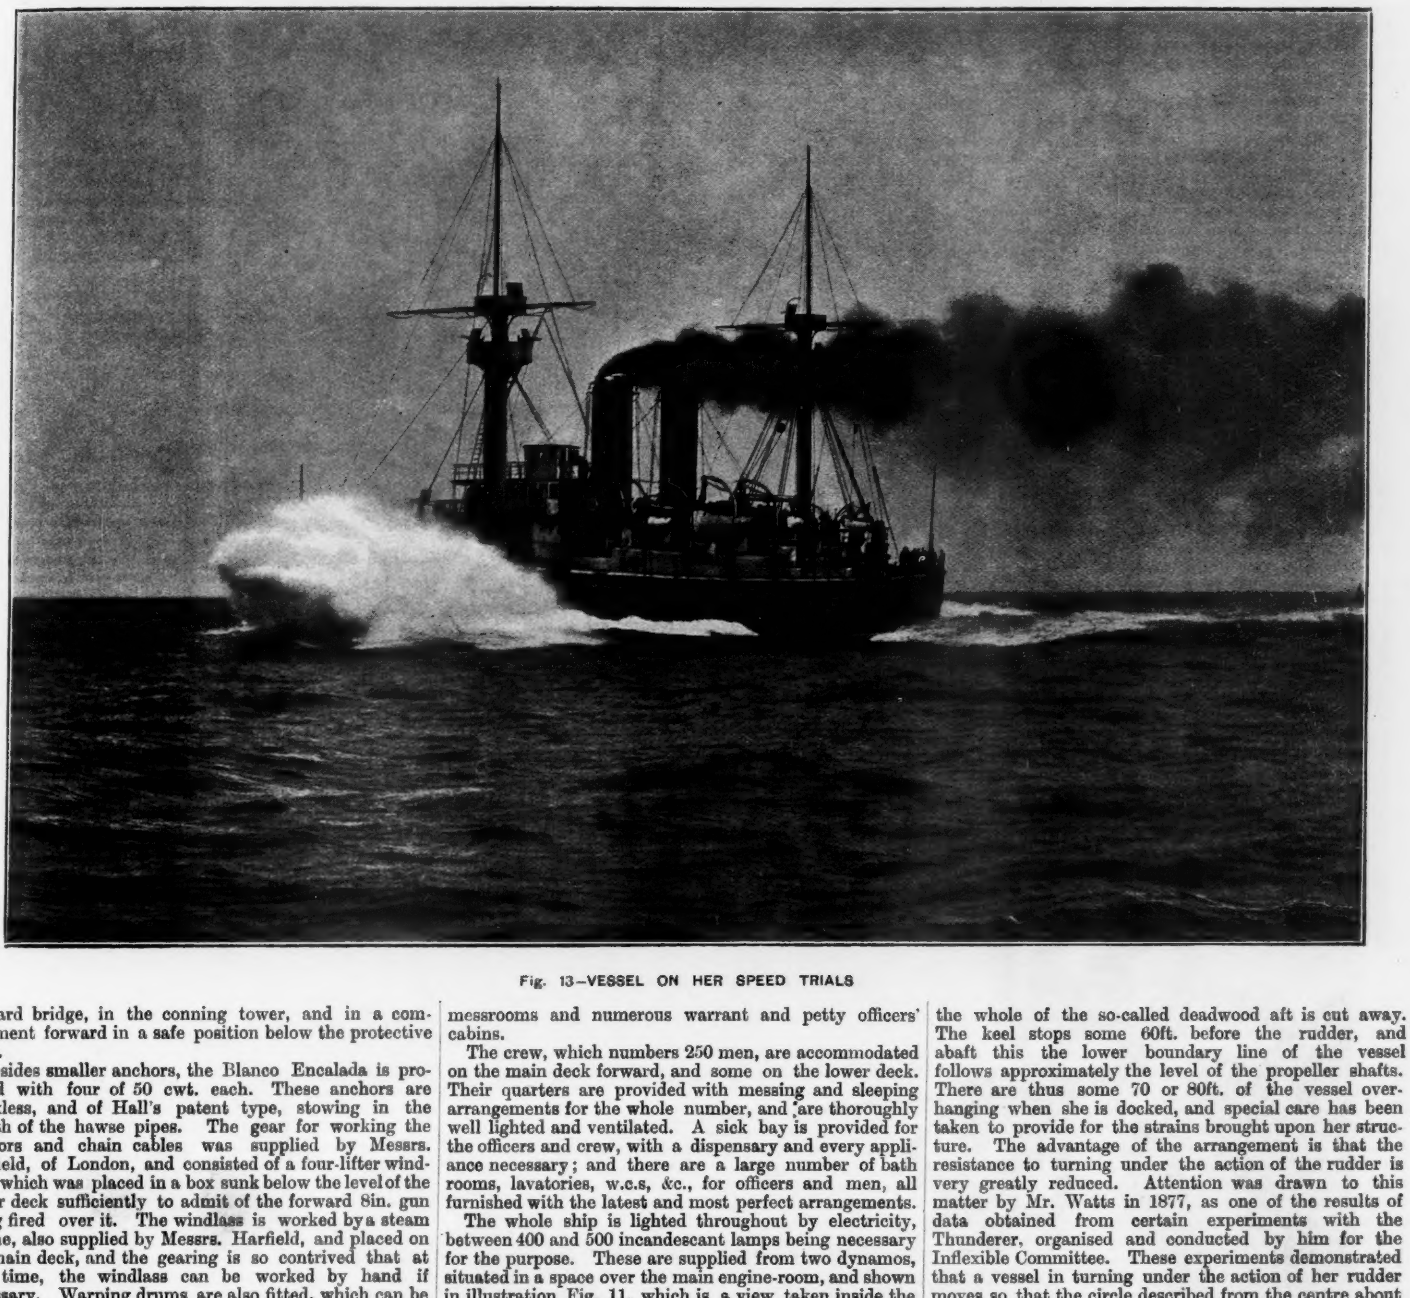

Fig. 13—VESSEL ON HER SPEED TRIALS

Besides smaller anchors, the Blanco Encalada is provided with four of 50 cwt. each. These anchors are stockless, and of Hall's patent type, stowing in the mouth of the hawse pipes. The gear for working the anchors and chain cables was supplied by Messrs. Harfield, of London, and consisted of a four-lifter windlass, which was placed in a box sunk below the level of the upper deck sufficiently to admit of the forward 8in. gun being fired over it. The windlass is worked by a steam engine, also supplied by Messrs. Harfield, and placed on the main deck, and the gearing is so contrived that at any time, the windlass can be worked by hand if necessary. Warping drums are also fitted, which can be worked with the windlass or independently. An auxiliary boiler is fitted on board for the purpose of supplying steam to the auxiliary engines, winches, &c., when there is no steam up in the main boilers. This boiler is of the vertical type, and is placed in a separate compartment on the lower deck.

The officers' quarters are arranged aft under the upper deck. The captain has a saloon, a dining-room, and two sleeping cabins. His saloon, of which we give an illustration—Fig. 7—is at the extreme after end of the vessel, and has a most comfortable, not to say luxurious, appearance. It is panelled throughout with Hungarian ash panels set in rosewood frames, between handsome carved teak pilasters. The ceiling is white, with wood mouldings on all the beams. The chairs and couches are upholstered in dark red morocco. Numerous sidelights in addition to a skylight make it always a light and cheerful room. The captain's dining-room—illustration Fig. 8—immediately joins his saloon, and is fitted up in the same style. Accommodation is provided in it for dining ten persons comfortably, and there is a pantry close at hand. His two bedrooms adjoin the other apartments, and are large and nicely-fitted rooms, with a bathroom and lavatory in communication with each. Forward of the captain's quarters are the other officers' cabins situated on both sides of the vessel. Illustration Fig. 9 is a view looking along the main deck aft, with the bulkhead and doors to officers' cabins, and a main hatchway coming down from the upper deck and leading below. This bulkhead is panelled with teak pilasters, and the doors have jalousies above and oak panels below. The rifles, as seen in the photo, are fitted in racks in between the cabin doors. The officers' cabins, which are amply large, are painted white and have handsome mahogany fittings, and are provided with every convenience, such as wash basins, tables, wardrobes, &c., and are well lighted. The ward room—seown in Fig. 10—is placed just aft of the engine hatch, on the starboard side, and is a very fine room, about 30ft. long by 24ft. wide. The large table seen in the photo accommodates fourteen people, and two other smaller tables, not shown, would seat about eight or ten more. The walls are panelled with maple, in teak framing, and the ceiling is white with mouldings on the beams. There are twenty-four officers' cabins, besides the midshipmen's and engineers' messrooms and numerous warrant and petty officers' cabins.

The crew, which numbers 250 men, are accommodated on the main deck forward, and some on the lower deck. Their quarters are provided with messing and sleeping arrangements for the whole number, and are thoroughly well lighted and ventilated. A sick bay is provided for the officers and crew, with a dispensary and every appliance necessary; and there are a large number of bath rooms, lavatories, w.c.s, &c., for officers and men, all furnished with the latest and most perfect arrangements.

The whole ship is lighted throughout by electricity, between 400 and 500 incandescant lamps being necessary for the purpose. These are supplied from two dynamos, situated in a space over the main engine-room, and shown in illustration Fig. 11, which is a view taken inside the main engine hatch. The dynamos were made by Messrs. Scott and Mountain, of Newcastle-on-Tyne, and besides lighting all the small incandescant lamps, they supply the current for the three search-lights which are placed, two on the forward bridge, and one on the after shelter, and are each of 20,000-candle power. The masthead and side lights are fitted to use oil or electric lights, and oil lamps are provided in the engine-room and stokehold, in addition to the electric light.

The engineer's workshop which we illustrate—Fig. 12—is situated in a convenient position on the lower deck forward, and is fitted up with a screw-cutting lathe, planing, and punching machines, grindstones, &c.

The ventilation of all compartments above the protective deck is obtained by natural means; but artificial ventilation is required for some of the compartments below, and fans are provided for the purpose: wherever an aperture occurs in a bulkhead to admit of ventilation between two adjacent water-tight compartments below the protective deck, automatic stop valves are fitted to prevent the flow of water in case one of the compartments becomes filled. The pumping arrangements and fire service are most complete, and besides the main steam pumps there are two 7in. Downton's hand pumps and two 5½in. Downton's. Altogether more than 2000 tons of water could be pumped out of the ship in an hour.

Two strong steel masts are provided, each carrying two military tops, which carry 1-pounder and machine guns. The main mast also supports the large derrick for hoisting in and out the 60ft. torpedo boat. A light fore-and-aft rig is provided, and on the foremast is a yard for signalling purposes.

We gave an account of the Blanco's speed trials in our issue of June 15th for this year. But this account would not be complete without a few particulars of her performances. With forced draught her engines developed 14,500-horse power, and the mean of several runs on the measured mile course off the Tyne, with and against the tide, was 22·78 knots, while, with natural draught, she steamed at 21·75 knots, with about 11,000-horse power. Her good manœuvring powers were displayed during the course of the trials, when she made a complete circle at full speed in three and three-quarter minutes, the diameter being 405 yards.

In the Blanco Encalada, as already explained, the whole of the so-called deadwood aft is cut away. The keel stops some 60ft. before the rudder, and abaft this the lower boundary line of the vessel follows approximately the level of the propeller shafts. There are thus some 70 or 80ft. of the vessel overhanging when she is docked, and special care has been taken to provide for the strains brought upon her structure. The advantage of the arrangement is that the resistance to turning under the action of the rudder is very greatly reduced. Attention was drawn to this matter by Mr. Watts in 1877, as one of the results of data obtained from certain experiments with the Thunderer, organised and conducted by him for the Inflexible Committee. These experiments demonstrated that a vessel in turning under the action of her rudder moves so that the circle described from the centre about which she turns, to touch her middle line, touches her middle line at a point considerably on the fore side of her centre of gravity, and it thus follows that the streams of water cross the after part of the ship at a greater angle than any other part, and in a direction so as to resist the turning, and the less the resistance opposed to these streams by the form of the ship, the smaller will be the circle in which the vessel will turn. As the result of this the after deadwood in the Conqueror and Polyphemus were cut way to a considerable extent for the purpose of reducing the resistance to turning.

Her behaviour amongst waves was remarkably steady, which was probably due in some measure to the bilge keels with which she is fitted. We give an illustration—Fig. 13—of her running at a high speed during the steam trials. There was a considerable sea at the time, and when going head to wind, every now and then a shower of spray was thrown up from her stem, and it was at such a moment that the instantaneous photo we give was taken. For a general broadside view of the Blanco we must refer to the full-page supplement we published with our issue of September 7th, 1894, which was from a photograph taken during the gunnery trials.

The Blanco finally left the Tyne on October 9th, 1894, under the command of Captain Munoz Hirtado, who was at Elswick during nearly the whole time occupied in the construction and fitting-out of the vessel, which he in conjunction with Mr. Forbes, also a member of the Chilian Commission, personally supervised, and throughout rendered great assistance to the officials, and won the esteem of all with whom he came in contact.

Of the ships in the list we give on page 506, of fast

# THE CHILIAN CRUISER BLANCO ENCALADA

MESSRS. SIR W. G. ARMSTRONG, MITCHELL, AND COMPANY, NEWCASTLE-ON-TYNE, BUILDERS

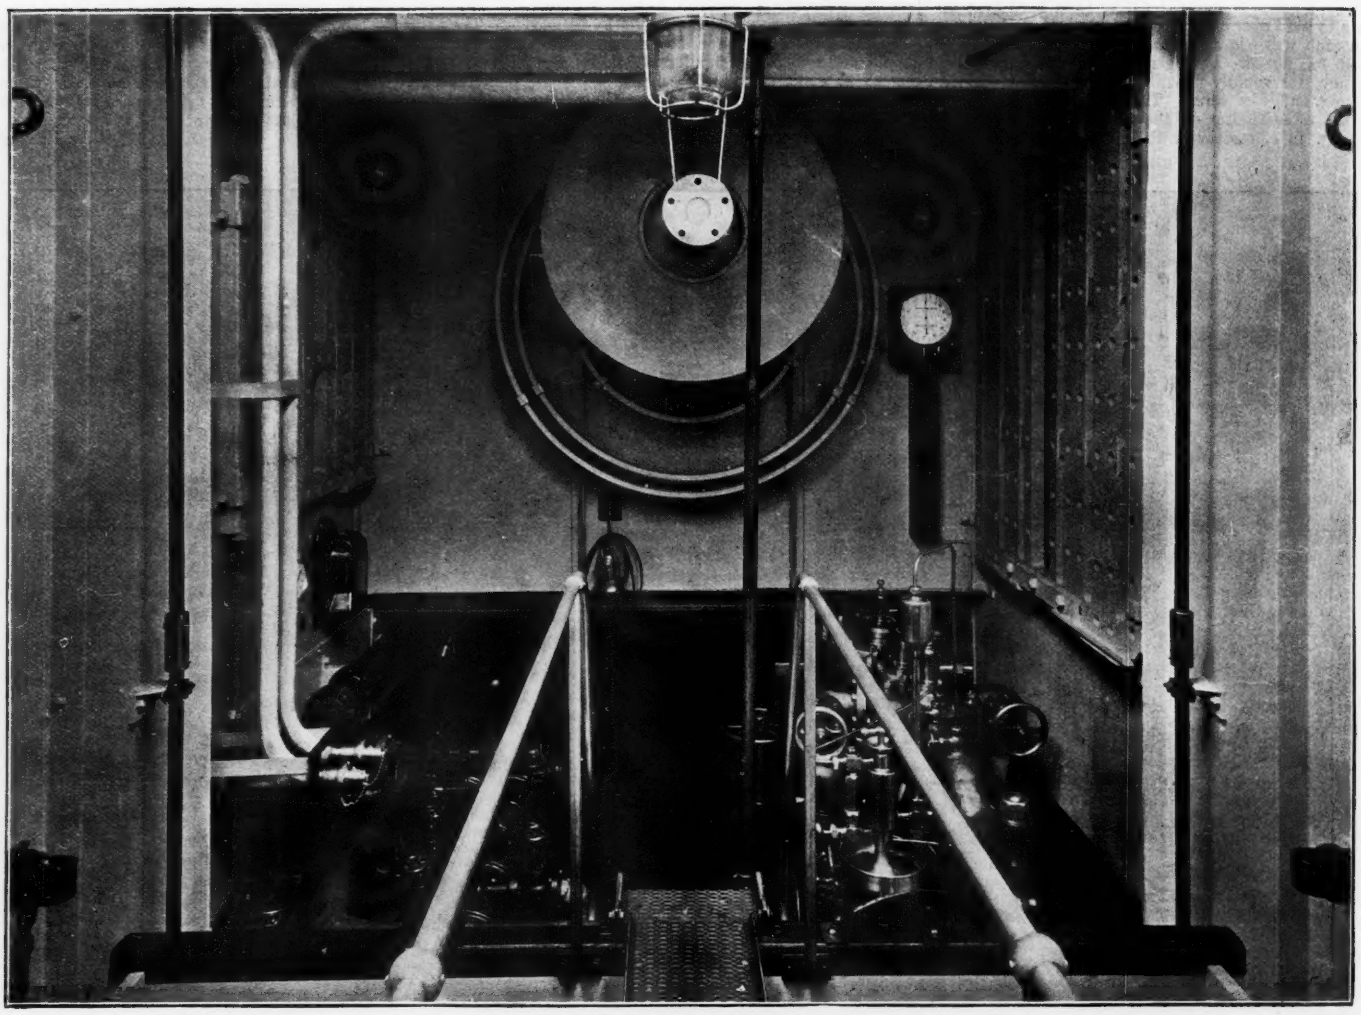

Fig. 11—VIEW INSIDE ENGINE-ROOM HATCH

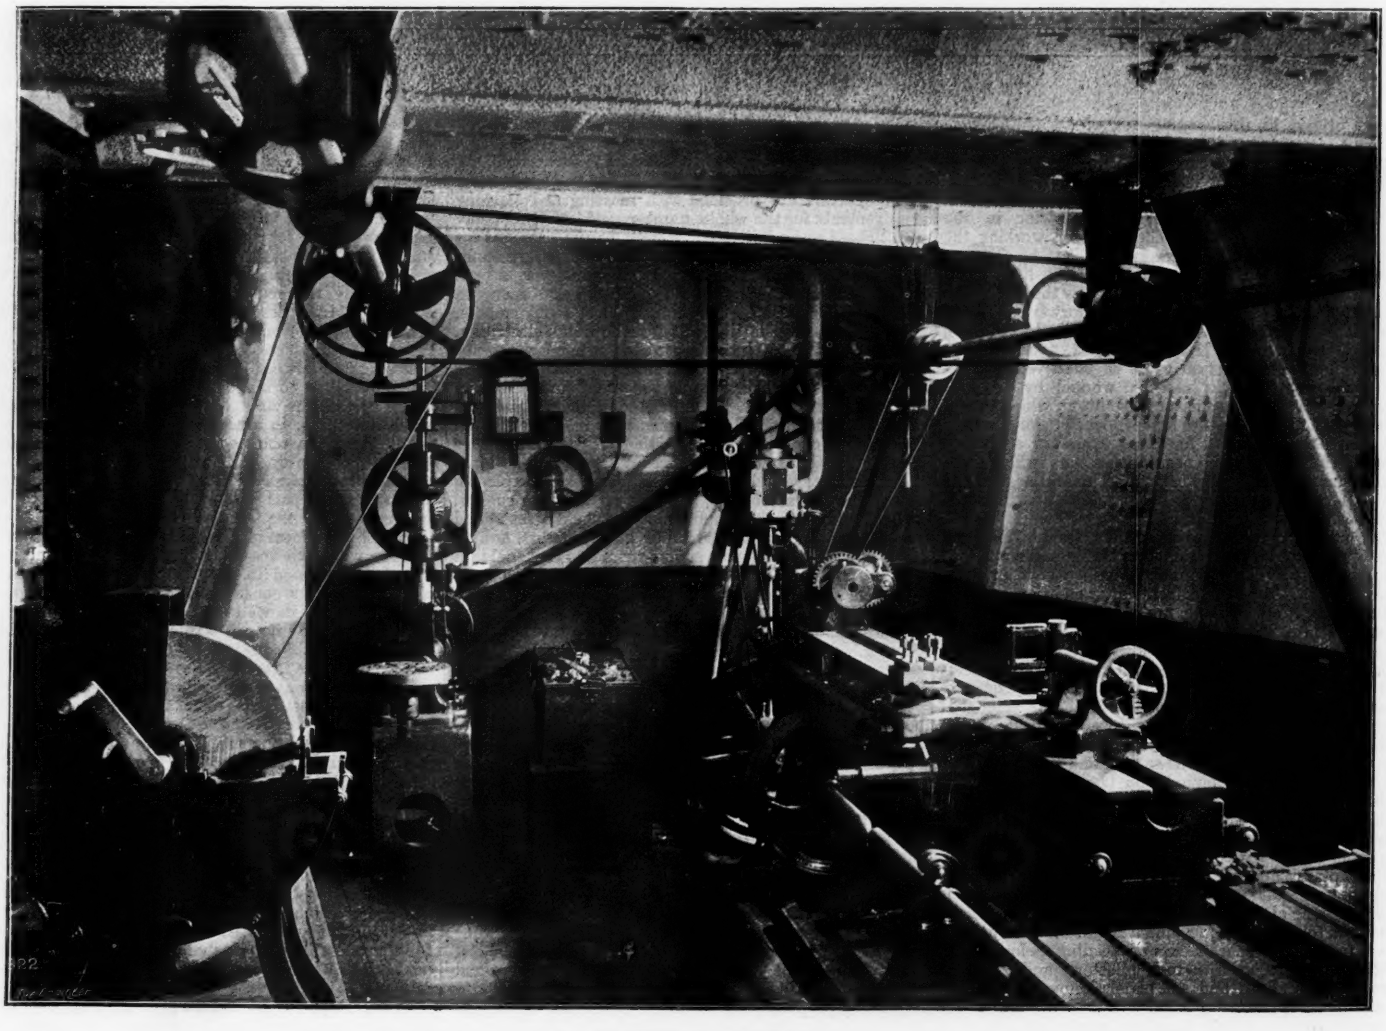

Fig. 12—ENGINEERS' WORKSHOP

Elswick built cruisers, five took part in the recent battle of Yalu; namely, the Naniwa, Takachiho, and Yoshino, on the Japanese side, and the Ching Yuen, and Chih Yuen on the Chinese side. In addition to these, there were other Elswick vessels, including the Tschao Yong and Yang Wai, in the engagement; but these have not been included in our table as they were not remarkable for their speed. It is difficult, with the somewhat meagre and unreliable information we have at present of the battle, to draw any very certain conclusions regarding the respective merits of the different types of vessels engaged. Taken as a whole, the Chinese fleet was distinctly superior in protection, and was armed with heavier guns; but the Japanese were faster than their rivals, and had more modern quick-firing guns; and it is pretty clear that the Japanese gained a great advantage at the very outset of the engagement, which enabled them, from the superior average speed of their ships, to out-manœuvre and circle round their slower opponents; this may partly have been due to the better tactics which were doubtless displayed by the Japanese commanders, but the evolutions performed would have been impossible without the fast cruisers which formed the most important part of the Japanese squadron.

This feature of the battle would have been even more fully emphasised had the Japanese been possessed of a few more cruisers like the Yoshino, which has a speed four knots in excess of any of the other vessels engaged. Another very noticeable point in the account of the battle is that no damage is spoken of to any of the engines, magazines, or steering gear in vessels of either side, showing that the curved protective deck, which on the Japanese side was the only form of armoured protection on any of the vessels except the Tschiyoda, was sufficient to defend the ship's vitals against the enemy's projectiles, which in this case ranged from the smaller quick-firing up to the 30½ cm. shells thrown by the guns of the Chinese armour-clads. Though the protective decks did such good service, showing that this system of defence is satisfactory for light fast cruisers, which cannot carry the weight of an armour belt on a small displacement, at the same time the impossibility of cruisers coping with armour-clads in battle was pretty clearly shown; for if the accounts we hear are to be believed, the armour belts of the Chinese battleships completely withstood all the fire directed against them, which at the same time made havoc of the superstructures and unarmoured portions.

One effect of the rain of shot and shell—which, as far as we know, has never been anticipated to such an extent as this engagement showed to be the case—was the setting on fire of nearly all the ships engaged. The Japanese seem to have been more successful in extinguishing the flames than the Chinese, who were probably not so well versed in fire drill; and the latter lost two ships, the Tschao Yong and Yang Wai, from this cause. This seems to point to the fact that the use of any inflammable material should be avoided as much as possible in the construction of war ships; with this small exception, the battle of Yalu seems to show that our naval architects have been working in the right direction, and that the fast cruisers of the Elswick type are most essential in a sea fight for quick manœuvring, but that armour-clads are absolutely necessary as the first line of defence.

On page 501 we give a portrait of Mr. Watts, the designer of the Blanco Encalada, and other fast Elswick cruisers. Mr. Watts was apprenticed in 1860 at the Royal Dockyard, Portsmouth, undergoing the superior course of instruction under Mr. Craddock, the master shipwright. From 1866 to 1870 he passed through the Royal School of Naval Architecture and Marine Engineering. On leaving this he received the appointment of draughtsman of Portsmouth Dockyard; but was shortly afterwards sent to Jarrow as an Admiralty inspector, in connection with the building of the Swiftsure and Triumph at Messrs. Palmer's yard. At the close of 1872 he was placed on the staff at the Admiralty, and was associated for several years with the late Mr. William Froude in experimental investigations on the forms of ships. While at the Admiralty Mr. Watts occupied several positions, and latterly that of constructor at Chatham Dockyard. He left the Government service in 1885, under an arrangement between Lord Armstrong and Lord George Hamilton, by which Mr. White left Elswick and took up the position of Director of Naval Construction at the Admiralty, and Mr. Watts took the position vacated by Mr. White at Elswick.

## "EIGHTY-FOUR MILES AN HOUR."

By CHARLES ROUS-MARTEN.

To most people it must seem strange that the question, "How fast can a locomotive run?" which has so often been asked—in the columns of THE ENGINEER and elsewhere—for many years past, still remains without an authoritative answer. It might have appeared certain that systematic and persistent attempts would be made to solve such an interesting problem. But the truth is, that, however interesting on scientific grounds, the problem does not possess much practical value. Locomotives have for nearly half-a-century proved themselves able to fulfil all practical requirements in respect of mere velocity. During the last twenty-five years the problem has been to run the greatest possible load for long distances over all gradients at a high sustained speed, not to run a light load at extreme speeds for a few miles on favourable grades. British railways are purely practical undertakings for commercial purposes, and there has been nothing to be gained by testing a question mainly academic in its nature.

The question, "How fast do trains run?" is almost daily receiving replies—of a kind. Responses come in rich abundance from the irresponsible amateur railway passenger. Readers are treated to an abundance of fabulous and virtually impossible locomotive feats, many given apparently in good faith, but manifestly based on some error of observation or record. As a recent instance may be mentioned the case of that American engine No. 999, which with the "Exhibition Flyer," was stated to have run a mile in thirty-two seconds, or at the rate of about 112 miles an hour. The same engine on that train was twice timed privately for me by two railway experts independently, both capable and trustworthy men well versed in engineering matters, and their results, obtained when the engine was presumably doing its best, fell short of these wild figures by about one-third! In another case a very eminent American engineer absolutely vouched for the alleged fact that one of his engines had attained 82·5 miles an hour on a level road with a heavy train; but when in reply to an expressed doubt he published his own recorded figures, these showed the maximum speed to have been only 67 miles an hour, while in one instance his figures represented the train as passing a second station half-a-minute before the one previous! When even trained observers fall into these errors, it is not surprising that amateur "speed cranks" tumble into the maddest whirlpools of blundering. It is by no means easy to time a fast train accurately. Mile posts are missed, or other posts are mistaken for them; watches are read off incorrectly in the extreme haste which is necessitated; three-quarters are taken as a mile, and so on, *ad infinitum.* For continuous accuracy at least two stop watches or chronographs are essential, and in many cases three are needed to give a continuous checked record.

Gross carelessness, too, is commonly displayed in relation to those speed records which are offered as genuine. Results are quoted as obtained by taking the time-table distances between stations as precise, instead of being as they usually are only roughly approximate, and straying often by fully a quarter-mile or more from strict exactness. Times are taken only to the even minute, fractions and seconds being ignored. As a consequence we get results which, to every competent observer, are self-evidently absurd, but which nevertheless are readily accepted by the world in general, and by the newspaper world in particular, as unquestionable scientific truths. In some cases it is impossible to explain the statements made on any theory of misconception, and the unpleasant conclusion is inevitable that the figures are utterly fictitious.

In the course of my extended examination of the railways of Great Britain, nine years ago, I paid particular attention to this question of maximum-speed possibilities, and carefully recorded the work done by every important express and fast train then running, making several tests of each train. The general results of those observations have often been referred to in the columns of THE ENGINEER. Briefly, I found that while speeds of 70 to 74 miles an hour were commonly attained on certain falling gradients, 75 miles an hour was only occasionally reached, and very seldom even slightly exceeded. The highest velocity that I noted in ordinary express work was about 76·3 miles an hour. Once or twice in special cases this maximum was slightly passed, but it is needless on the present occasion to enter into details of past performances, as the best of these are entirely eclipsed in my more recent experience.

During the past eighteen months I have made at intervals a very large number of observations on the English railways, through the courtesy of the respective authorities, with a view mainly to a comparison between the locomotive work of the present day and that of nine or ten years ago. I have devoted much special attention to this question of speed maxima, and have obtained some very interesting results. My timings have been done either with three chronographs, or with two chronographs and a watch. My plan has been to use two chronographs for successive miles or quarter-miles while the highest speed was being run, the third, or the watch, being employed as a check, to take the longer distances, of so many miles, or from station to station, the records being subsequently collated and compared, almost invariably with the result of agreement within one or two tenths of a second.

My earliest experiments on this occasion were made on the London and North-Western Railway, with Mr. F. W. Webb's famous engine Greater Britain. The results have been published in THE ENGINEER. It will be remembered that Greater Britain in two instances easily attained a speed of 78·2 miles an hour, and was manifestly capable of considerably exceeding that rate, but that this was precluded by the fact that the train was already in advance of time, so that "easing off" became imperative. There was no opportunity of ascertaining the engine's full capabilities in the way of speed, but I have no reason to doubt her ability to equal anything which has been done by any other engine now running.

It was not long before this maximum of 78·2 miles was surpassed. Testing the 7.15 a.m., 9.45 a.m., and 4.15 p.m. down trains on the Great Northern line, I soon obtained unquestionable instances of speeds ranging from 79·1 to 79·5 miles an hour, and similarly on the up expresses of that railway, due at King's Cross respectively at 10.40 a.m. (Mondays only), 6.15 p.m., and 9.20 p.m. The engines were both classes of "singles"—the 8ft. 1in. with outside cylinders, and the 7ft. 7in. with inside cylinders. The loads ranged from six to ten coaches; the gradients were 1 in 200 to 1 in 150 falling. Like speeds were attained by a Midland 7ft. 4in. single, with a load of twelve coaches, during a descent of 1 in 132 to 1 in 120, and by a North-Eastern single compound, with a heavy train of sixteen coaches, down an incline of 1 in100.

The first clear case of 80 miles an hour was recorded by me on the Great Northern line with an 8ft. single down the Abbott's Ripton bank of 1 in 200 for five miles. This was on the last mile at the foot of the incline, the two previous miles having been done at 76·5 and 78·2 respectively. That was promptly rivalled by a 7ft. 7in. single, and by other "eight-footers," both on the down line near Arlesey, and on the up line near Essendine. But for a while I did not meet with any instances on other lines. When these did come they went still farther, and in its turn the Great Northern was for a while distanced in the race.

Most people would be inclined to expect, reasoning *à priori,* that if a speed of 80 miles an hour could be beaten, it would be by a large-wheeled "single" engine. Certainly I should have anticipated this, judging from my former experiences. But such was not the case. To begin with, the Great Northern maximum was equalled by two 6ft. 6in. coupled London and North-Western engines of the Precedent class. Going down the incline which extends from Shap Summit to Carlisle, with a train of seventeen coaches, these two engines attained a speed of exactly 80 miles an hour for three miles just before slackening for Carlisle, each successive mile being run in just 45 seconds. At Carlisle, two of the 6ft. 6in. coupled Caledonian engines — Carbrook class—took on the train. After some very remarkable performances, which I may deal with under another heading, one of these engines, with the seven Edinburgh coaches, going down the Cobbinshaw bank of 1 in 100, managed to do a mile in 44·4 seconds, equal to 81·1 miles an hour. On the return journey the same engine and load got up to 80 miles an hour down 1 in 200 near Gretna. But this was eclipsed by the London and North-Western, between Carlisle and Preston. Some time having been lost by a signal stop, the Shap bank of 1 in 75 and 1 in 147 was descended by the two 6ft. 6in. coupled Precedent engines, with sixteen coaches, at an exceptionally rapid pace. After passing the thirty-seventh mile-post—reckoned from Lancaster—half a mile from the summit, the successive miles were run in 56, 49, 45, and 44 seconds, the next being slightly slower, approaching Tebay Junction. The speed did not rise again until Grayrigg had been passed, but it then again attained the same rate as before, of a mile in 44 seconds, equal to 81·8 miles an hour, which was maintained for several miles down the gradient of 1 in 125. The entire journey from Carlisle to Preston, and thence to Euston, was in many respects remarkable as a locomotive feat, but a description of it would not come within the scope of my present subject, and I must leave it for another occasion. The fact, however, is in itself notable that fully six miles of the distance were run at a speed of 81·8 miles an hour, and this by engines with 6ft. 6in. coupled wheels, not by the more popular large-wheeled "singles."

So long did this rate of velocity remain my highest record, that it began to appear as if this really was the maximum possible with engines of existing types. That London and North-Western maximum was quickly rivalled by engines on several other lines, and I obtained a large number of records of 81·8 miles an hour. The Midland was the first to reach the same point. A 7ft. 4in. single on the 10.35 a.m. down Edinburgh express, and another on the 1.30 p.m. dining-car Scotch train, each touched the "magic eighty," the former approaching Bedford, the latter approaching Nottingham—gradients 1 in 200 down. Then a 7ft. 6in. single on the 5.40 p.m. down, near Bedford, attained 81·8, and a 7ft. 4in. on the up Glasgow express—due St. Pancras at 7.25 p.m.—performed the same feat with a load of ten coaches at no fewer than three points in the run from Leicester to London, viz., descending respectively the banks past Isham, Sharnbrook, and St. Albans, ranging from 1 in 177 to 1 in 100. A like engine did identical work on the up dining-car express on the same lengths of the line, and several instances occurred with various trains between Ampthill and Bedford. All these were with "single" engines of either the 7ft. 4in. or the 7ft. 6in. class. But in one case a 7ft. coupled engine of the 1750 class, with the 2 p.m. down train, succeeded in reaching 81·8 miles an hour with a load of nine coaches, down 1 in 200. The Great Northern soon followed suit, and both the 8ft. and the 7ft. 7in. classes of engines proved that they too could manage 81·8 miles an hour, with loads of eight to ten vehicles, down the long descending gradient which extends from Stoke Box past Tallington.

Nor were other coupled engines than those of the London and North-Western and Great Northern lines behindhand in this respect. On the London and South-Western one of Mr. Adams' new 6ft. 7in. coupled engines of the 557 class, having 19in. by 26in. cylinders, and 175 lb. steam pressure, ran at 81·8 miles an hour for two miles down the incline of 1 in 80 between Okehampton and Yeoford. The run between those stations—14½ miles—is timed to be done in 16 minutes, or at the rate of 54·3 miles an hour. In this instance it was accomplished in 14 minutes 14 seconds, although part of the distance is an ascending grade of 1 in 80. On the Caledonian Railway the Edinburgh Exhibition engine Carbrook twice ran a mile in 44 seconds down a bank of 1 in 100 with a train of seven coaches. It is noteworthy in this connection that the speed at which the American engines, which were said to have run 102 and 112 miles an hour respectively, were actually timed by careful and unbiassed English observers, was in each case the same as that recorded by me with these English engines, viz., 81·8 miles an hour. But it is only fair to add that each observer expressly informed me that in his judgment his respective engine was not doing its utmost at the time, and could, if "pushed," have attained a slightly higher velocity. I note this simply as an expression of personal opinion, but subsequent experiences have tended materially to support the conclusion arrived at. I may add also that capable and trustworthy information has been furnished to me of the same maximum having been reached by the Caledonian 7ft. single, No. 123, by a Lancashire and Yorkshire 7ft. 3in. coupled—Mr. Aspinall's—by a 7ft. compound on the London and North-Western, and by one of Mr. Adams' 7ft. 1in. coupled on the London and South-Western.

On one occasion I made a special effort to exceed that apparently fixed limit of speed. Travelling on one of the newest of Mr. P. Stirling's splendid 8ft. 1in. single express engines, we attained 80 miles an hour down the gradient of 1 in 200 near Little Bytham. In reply to my question, the engine driver, a very intelligent man, said that in his opinion the engine was doing "about her best." He gave however, a little more steam experimentally, when the speed rose to 81·8. But a second addition of steam was followed by a drop to 78·2, apparently due to back pressure. The line then became more level and no increase could be obtained. It is my impression, in view of later occurrences, that had the first additional steam been given at an earlier and steeper portion of the incline, the maximum of 81·8 might have been passed. However, this was not done, the driver's knowledge and practical experience of the obstructive effect of back-pressure when too much steam is admitted to the cylinders, having led him to err on the side of excessive caution. Hence, this remains my maximum so far with the 8ft. 1in. engines.

It may be interesting at this stage to set forth in tabular form a list of the various classes of engines with which I recorded a speed of a mile in 44 seconds, or 81·8 miles an hour:—

| Railway. | Locomotive superintendent or designer. | Dimensions of cylinders. | Dia. of driving wheels | Single or coupled. | Steam pressure. |
|---|---|---|---|---|---|
| | | in. in. | ft. in. | | lbs. |
| †L. & N.-W. | F. W. Webb | 17 × 24 | 6 6 | Coupled | 150 |
| *Gt. Nor. .. | P. Stirling | 18½ × 28 | 8 1 | Single | 160 |
| † „ .. | „ | 18⅞ × 26 | 7 7 | „ | 160 |
| Midland .. | S. W. Johnson | 18½ × 26 | 7 6 | „ | 160 |
| „ .. | „ | 18 × 26 | 7 4 | „ | 160 |
| „ .. | „ | 18 × 26 | 7 0 | Coupled | 160 |
| *L. & S.-W. | W. Adams | 19 × 26 | 6 7 | „ | 175 |
| Caledonian | D. Drummond | 18 × 26 | 6 6 | „ | 150 |

* Outside cylinders; all others are inside. † Radial leading axles; all others have leading bogies.

In all these cases there was remarkable steadiness of running and freedom from oscillation; in fact, as I had noticed in my experiments of nine years previously, the steadiness of running was often superior at the highest velocities to that experienced at a slower rate of travelling. The impression conveyed was that, in respect of stability on the road, this improved as the speed augmented. It is needless to say that this applies solely to roads suitable for speed—well and substantially laid, with heavy rails and plentiful sleepers, and free from sharp curves and facing points. On such lines there would be no danger in running at the speeds fabulously reported of some American engines, could these be actually attained in practice.

The first instance of a higher speed being attained than a mile in 44 seconds, for which I can absolutely vouch, occurred somewhat unexpectedly to me, and, I suspect, unconsciously so far as the engine-drivers were concerned. The 3 p.m. Leeds fast express from St. Pancras left with two engines, both 7ft. 6in. singles—one a return pilot "going home"—the load being only eight coaches. Now, as either of the engines could probably have kept time with double that load, it is obvious that there was a large margin of locomotive power available. The train was much hindered at first by a strong side wind, and a loss of fully two minutes was caused by a signal check at Elstree Tunnel. The drivers evidently considered that they must "push ahead" to make up lost time, and after Toddington summit—33¾ miles—was passed, and the sixteen-mile descent to Bedford entered upon—the side wind by this time being lost—the speed rose in a very remarkable way.

By the time Flitwick was reached the speed had risen to 76·5 miles an hour; approaching Ampthill it was 77·1. Then followed the sudden drop in speed which I have invariably noticed near Ampthill and through the tunnel. On emerging from the tunnel the rate was only 70·6, but it then steadily and rapidly rose. Speeds of 75·0, 76·6, 77·4, 78·2, 79·1, 80·0, 81·1, and 81·8 were successively shown by the two chronographs, the last being reached at the forty-fifth mile-post. But the speed still continued to rise, and at the forty-sixth post had attained the rate of 83·7 miles an hour, at which it continued for two miles, each being done in 43 seconds. Steam was shut off at 48 miles, and the velocity gradually fell until Bedford was passed at the usual reduction to 10 miles an hour. The third chronograph showed that a distance of 9½ miles, up to the time of shutting off steam, was run in 7 min. 13·4 sec., or at the average rate of 78·9 miles an hour, including the falling-off to 70 miles an hour, and the gradual recovery after Ampthill. During the fastest part of the running I obtained two doubtful timings of a quarter-mile in 10·7 seconds, which would give a slightly higher rate, but owing to the intervention of trains passing in opposite directions, I cannot positively vouch for these, and therefore do not put them forward on this occasion. The fact, however, remains that a speed of 83·7 was unquestionably and indisputably maintained for two successive miles on a falling gradient of 1 in 200.

There was no wind at the time, and the rails were in excellent order, while the train was composed of mostly uniform rolling stock, and, being of moderate length, had no "tail" to "wag." Nothing could exceed the smoothness of the travelling. There was no appreciable oscillation whatever, and the whole train seemed to glide along as if on ice or on oiled runners. The passengers did not appear at all conscious of travelling at exceptional speed, and no remark was made. On other occasions when going at 55 to 60 miles an hour down steep gradients and round sharp curves, I have heard many exclamations at the "fearful speed," which, in fact, was doubtless less safe relatively than was this 83 miles an hour on so eminently favourable a length of line. It may be worth while to add that the complete run from Kentish Town to Kettering—70½ miles—was done in 76 minutes 29 seconds, including a loss of three minutes by two bad signal checks—near Elstree Tunnel and Irchester respectively—thus leaving the net time 73 minutes 29 seconds.

Curiously enough the same week furnished a second instance of the same exceptional speed being run by an engine of the same class on the same line. This was on the 10 a.m. Glasgow express with nine coaches in showery weather, with light head wind during part of the distance, not, however, on the length where the best speed was achieved. There was a Pullman car in the train, which tended to improve the steadiness in running.

On this occasion the remarkable run of 12 miles—36th to 48th mile-post—in 9 minutes 14 seconds was made by the engine, including the customary diminution of speed near Ampthill. Unfortunately, owing to the intervention of trains on the up or relief line, several intermediate posts could not be taken on the best part of this interesting run, but several successive quarter-miles were run in 10·7 seconds each, equal to a speed of 84·1 miles per hour.

Such performances having been accomplished by the Midland single-wheel engines, there seemed no valid reason why the Great Northern engines, with practically identical dimensions and power, should not be able to show equal speed records, so I made a number of experimental trips with the object of determining this point. It did not long remain in doubt. One of these inside-cylinder engines, with 7ft. 7in. single driving wheels, got up to 82·5 miles an hour descending the bank of 1 in 150 and 1 in 200 which extends from near Nostell toward Doncaster. Three successive runs with an engine of this class, which has larger cylinders than the others—18⅞in. diameter—gave some interesting results. The first was somewhat impeded by side wind, nevertheless a speed of 81·1 miles per hour was reached; the load was seven coaches, weighing approximately 100 tons. In the second trial the load was the same, but the weather was more favourable and higher figures resulted. After passing Corby at 70·6 miles an hour, the speed rapidly increased to 73·5, 75·0, 76·6, 78·2, 80·0, 81·8, 82·4, 83·7, and finally 84·1 miles an hour, several successive quarter-miles being covered in 10·7 seconds apiece, and two miles consecutively in 42·8 seconds each. The third trial had the advantages of perfectly calm, fine weather and a load lighter by one coach, but the results were in most respects identical. Again a speed of 84·1 was reached and maintained for two miles. This maximum was, however, attained somewhat more quickly with the lighter than with the heavier load, and the speed diminished rather more slowly as the falling gradient merged into a level road. But the difference was very small, only 3 seconds gained between Stoke Summit and Bytham, and 2 seconds gained between Essendine and Tallington. The time for the 3 miles 52 chains from Bytham to Essendine was in each case the same, and the quickest by 5 seconds ever recorded by me, viz., 2 minutes 39 seconds, equal to an average rate of 82·6 miles an hour. As in the other cases quoted, there was in these instances entire and remarkable steadiness alike on the footplate and in the train, for I tested both, travelling on the footplate in one case, and in the rear coach in the other. Even the most nervous passenger, who writes indignant but silly and ignorant complaints about "dangerous" and "alarming" speeds, could not have discovered the slightest grievance in the swift but utterly smooth running of these Great Northern and Midland trains that proved the feasibleness of travelling with complete safety at the rate of 84 miles an hour.

NOTE.—Distances are from official tables. * Slack to ten miles an hour. † Signal stop.

The leading dimensions of the engines which attained 84·1 miles an hour may be summarised as follows:—

| Railway. | Class. | Cylinders. | Diameter driving wheel. | Mean pressure. | Bogie or rad'l axle |
|---|---|---|---|---|---|
| Midland ... | Single | 18½ × 26 | 7ft. 6in. | 160 lb. | Bogie |
| Gt. Northern | Single | 18⅞ × 26 | 7ft. 7in. | 160 lb. | Radial |

It will be noticed the former of these two Great Northern runs gives the excellent performance of 105⅓ miles, from Grantham to King's Cross, in 1 hour 52 minutes 57 seconds, and the latter the still better work of the same distance in 1 hour 55 minutes 3 seconds, with three intermediate signal stops, absorbing 4 minutes 46 seconds, bringing down the actual travelling time to 1 hour 50 minutes 17 seconds, while the further loss by three extra stoppings and startings was fully 6 minutes, making the virtual net time 1 hour 44 minutes 17 seconds.

In the annexed speed tables we give the "logs" of the respective trains' running.

The question will naturally suggest itself whether the engine was really doing its utmost when this speed of 84·1 miles an hour was attained. My own opinion is that the limit of the engine's capacity in the way of actual speed was, if not reached, yet very closely approached. The driver, who, as in the other case referred to, was a very intelligent and capable man, was of opinion that by giving the engine a little more steam it might have been possible to reduce the time per mile by a second or nearly so, provided he received special authority to press the engine to her utmost capacity. It seemed to me, however, that she was already taking as much steam as she could profitably utilise, and that to give more would have been simply to invite obstruction by back-pressure, as in other experiences. As it was, the engine had just sufficient load to enable her to put out her full-power and utilise the steam to the best advantage. At the same time I freely admit that her driver ought to be best acquainted with his engine's idiosyncrasies, and that he may be right in his view, although I gather that so far it is based solely upon theory, as the higher speed does not appear to have been hitherto authentically recorded.

It may be worth while to remark that all the engines which have exceeded the maxima recorded by me nine years ago have increased steam pressure, viz., 150, 160, or 175 lb., as against 140 lb. or less. That is the one salient difference between then and now. Cylinder diameters are larger in some cases but not in all, or even in the majority of instances, and my almost invariable experience on the present occasion has been, that while the speed maximum is higher than it was nine years ago, it is attained more gradually than then, a fact which probably points to more careful and economical development of the engines' powers on the part of their drivers, who avoid prematurely forcing or hurrying them up to their highest velocity. I suspect also that a freer exhaust may now be provided, in some cases, at any rate, thus reducing back-pressure.

It is not intended at all to convey the idea that other engines and other railways are unable to equal the performances above set forth. On the contrary, I see no reason whatever to doubt that some of the engines on most of the leading English lines are fully capable of performing equally fast work. But I am simply recording what came under my own personal notice, and hitherto I have never yet attained a speed of 80 miles an hour on any British standard-gauge railway excepting those specified in these notes. The present prevalent policy on most of the British lines seems to be rather to make fast average time by "forcing the pace" uphill, even at the cost of additional consumption of fuel, than to utilise the force of gravitation on moderate descending gradients by running at the highest speeds downhill. This, of course, is purely a question of policy, the discussion of which does not come within the sphere of the present article. But the results of my investigations go conclusively to show that no valid argument against this utilisation of a valuable force exists on the score of danger or unsteadiness, and that no additional risk or discomfort is incurred by descending moderate gradients on well-laid and fairly straight roads at speeds of 75 to 84 miles an hour.

Some of the engines of the classes referred to in this article have been illustrated in THE ENGINEER, December 16th, 1892; September 20th, 1889; December 23rd 1887; April 21st, 1892.

## THE ATLAS WORKS, GLASGOW.

Although we have already illustrated and described more than one of the leading locomotive works in the kingdom, this description of the Atlas Works of Messrs. Sharp, Stewart, and Co., is exceptional in the sense that it is the first establishment which has, since its commencement, been conducted entirely by private capital. To engineers the name requires no introduction, on account of its close connection with locomotive engine progress; and even to those of our readers who are not exactly engineers—if that title should possess any exact meaning in the minds of any of them—we feel that an explanation would be superfluous on account of the widespread circulation of the firm's name-plates. At the same time we here give a brief history which may interest some of an archæological turn of mind. The firm was originally styled Sharp, Roberts, and Co.—that is to say, Thomas Sharp and Richard Roberts entered into partnership in 1828 for the purpose of manufacturing cotton-spinning machinery; their works being situated in Falkner-st., Manchester. They pursued this branch of industry for some time, taking out patents for improvements in spinning machinery, Roberts' self-acting mule meeting with extraordinary success. They also went in for card-making and block-printing machinery, though no large development was attained in these last two branches. It was just about this time—that is, between 1830 and 1840—that the demand for machine tools sprung up, and the genius of Roberts, aided by the enterprise of the Brothers Sharp, soon found means of extending this manufacture both at home and abroad. The machines for planing, slotting, wheel-teeth cutting, punching and shearing, and the numerous lathes invented and adopted by Roberts secured for the firm the high reputation which it still retains.

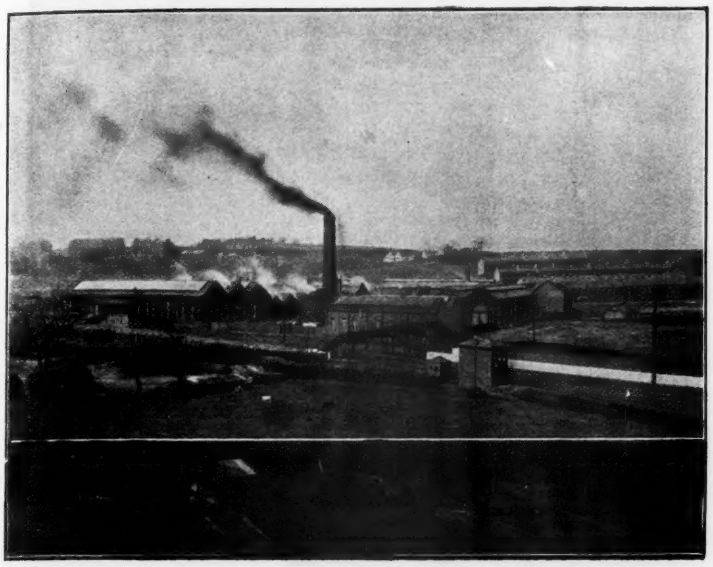

Fig. 3—MESSRS. SHARP, STEWART, AND CO.'S WORKS FROM THE SOUTH

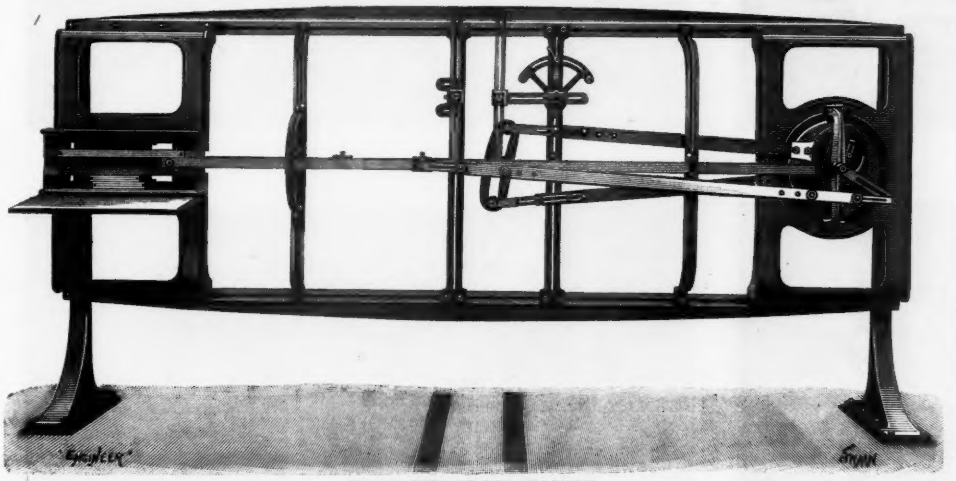

Fig. 6—SETTING-OFF MACHINE

It was in 1834 that the building of locomotive engines was commenced, the first four productions being of the bell-crank and lever type, all exactly alike. No. 1 was an experimental engine with 11in. cylinders and 16in. stroke; diameter of boiler 3ft., and diameter of driving wheel 5ft., and ran on the Liverpool and Manchester Railway. Nos. 2, 3, and 4—the Hibernia, Manchester, and Britannia—were supplied to the Dublin and Kingstown Railway. The Hibernia is shown in Fig. 1, side by side with the engine which is now doing the duty which her predecessor did sixty years ago—the two forming a striking contrast between past and present.

The modern tank engine, Fig. 2, was supplied to the Dublin, Wicklow, and Wexford Railway in 1893 by Sharp, Stewart, and Co., and has 5ft. 3in. wheels with 18in. cylinders, with 2ft. 2in. stroke. The heating surface is 1226½ square feet, total weight 55¼in. tons, and tank capacity 1200 gallons.

To return to our history. In 1842 Thomas Sharp, the senior partner, died, and in the following year Roberts retired from the firm, continuing business alone at Falkner-street, the other partners taking their business to the Atlas Works. The firm was also reconstructed by the admission of Mr. John Robinson, who had been a pupil of the old firm, and he, with Mr. John Sharp and Mr. Thomas B. Sharp, continued the business under the style of Sharp, Bros., and Co. Under their management the manufacture of locomotives became a leading feature, accompanied by that of machine tools, while the cotton and textile machinery was given up. It was not till 1852 that Mr. C. P. Stewart's name appeared. This gentleman, who had been a pupil of the celebrated marine engineers, Seward and Co., succeeded Mr. John Sharp, the senior partner, then retiring. The business continued to prosper, and shortly afterwards Mr. T. B. Sharp retired as well, to be succeeded in his turn by Mr. Stephen Robinson.

It was then that the manufacture and exploitation of Giffard's injector became an important adjunct to the business. This arose from the observance by Mr. Stewart of one of these appliances at work in a steamboat in the Mediterranean, the utility of which was so apparent that he made arrangements with M. Giffard for the manufacture and sale of his invention, which practically revolutionised locomotive boiler feeding.

In 1863, in accordance with the Limited Liability Act just passed, the partnership was converted into a limited company, the three partners remaining in the business as managing directors, C. P. Stewart as chairman, and John Robinson as vice-chairman. Mr. Stewart died in 1882, Mr. John Robinson succeeding to the chair, the business still being carried on at the Atlas Works, Manchester. Owing to the expiration of the lease of these premises, negotiations were opened in 1887 for the acquiring of premises and plant in Glasgow, which had been till then known as the Clyde Locomotive Works, the works, in fact, with which we now have to deal under an altered name. The antecedents of the Clyde Works were briefly as follows:—They were founded by Mr. W. Montgomerie Neilson—formerly principal partner in Neilson and Co.'s Hyde Park Works, Glasgow—in conjunction with other gentlemen. The company was incorporated in March, 1884, and commenced operations in 1885, and their orders came chiefly from the Highland Railway Company, one of eight express engines built for this line being exhibited at the Edinburgh Exhibition in 1886.

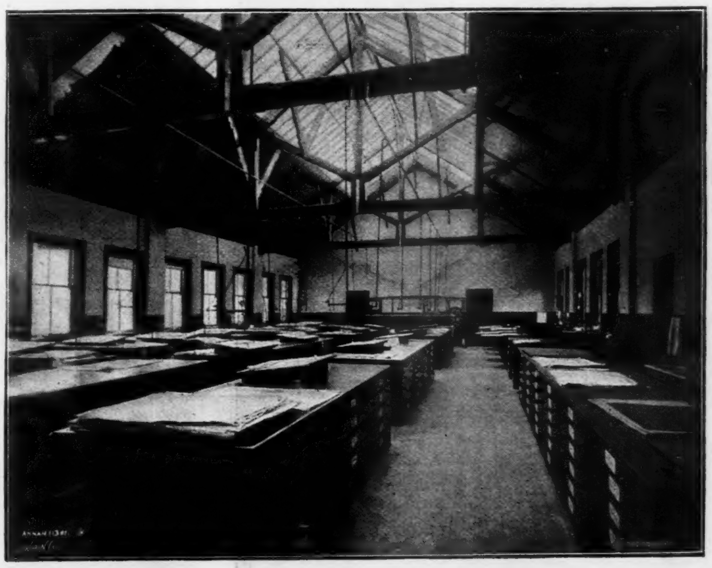

Fig. 5—DRAWING-OFFICE

The amalgamation with the Clyde Locomotive Company was completed, and the new works were started in January, 1888; Mr. John Robinson remaining chairman, and a board of directors being chosen to represent both the English and Scotch capital of the concern.

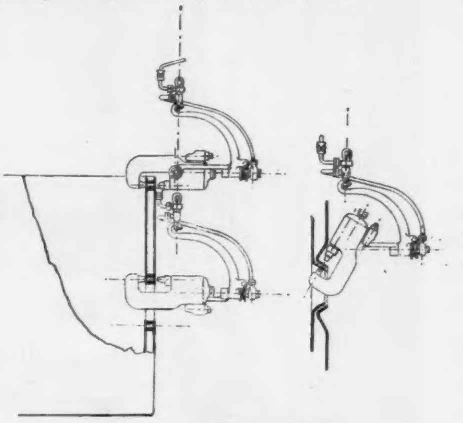

Fig. 9—FIRE-DOOR RIVETER

Springburn, where the Atlas Works now are, lies north-east of Glasgow, and can be reached from that city in fifteen minutes by the North British local trains, although it is actually within the municipal boundaries.

Fig. 3 is a general view of the works, reproduced from a photograph taken some while back, before the present offices were built—which are a great improvement—but otherwise than this the photograph is accurate. We give a plan of the premises in Fig. 4.

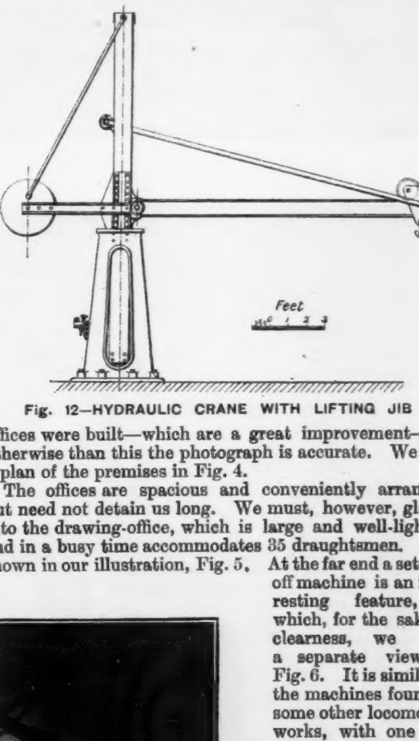

Fig. 12—HYDRAULIC CRANE WITH LIFTING JIB

The offices are spacious and conveniently arranged, but need not detain us long. We must, however, glance into the drawing-office, which is large and well-lighted, and in a busy time accommodates 35 draughtsmen. It is shown in our illustration, Fig. 5. At the far end a setting-off machine is an interesting feature, of which, for the sake of clearness, we give a separate view in Fig. 6. It is similar to the machines found in some other locomotive works, with one exception, that being the manner in which the excentric pulleys are placed on the shaft. In all cases which we have hitherto met with these pulleys are together side by side, as they are on the finished engine. The trouble with this arrangement has always been, when dealing with the outer excentric, the necessity of using a square to read off the figures on the graduated disc. Here we have the disc graduated on both sides, and the angles of both excentrics can be read with equal accuracy.

A room adjoining is a separate tracing department, where there is nothing particularly attractive — excepting, of course, the lady trecers employed therein. They appear to do the work as

We cannot do better than begin with the boilers, as any attempt to follow the growth of a locomotive, taking each phase in its manufacture in a definite order, must prove futile—simply because there is, so to speak, no common starting point. A locomotive is not like a sausage. Were we dealing with a sausage factory, we should feel no doubt about our starting point. But here there is unfortunately no pig. In the following description, therefore, we must imagine ourselves to be acting as our readers' cicerone, taking the features of interest in the order in which they would be presented to a visitor making a personal tour of inspection.

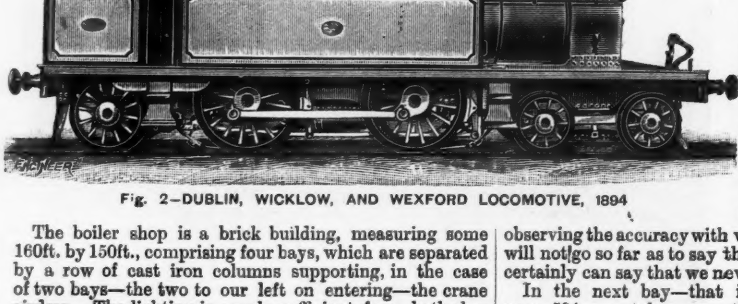

Fig. 2—DUBLIN, WICKLOW, AND WEXFORD LOCOMOTIVE, 1894

The boiler shop is a brick building, measuring some 160ft. by 150ft., comprising four bays, which are separated by a row of cast iron columns supporting, in the case of two bays—the two to our left on entering—the crane girders. The lighting is amply sufficient from both skylights and side windows, as will be seen from Fig. 7 on page 504. There are two overhead travelling cranes by Craven Brothers, the largest of which is capable of lifting ten tons on a 33ft. span—both rope driven. In addition to these there are the necessary jibs over the hydraulic riveters, the largest of which, with a 14ft. rake, is in the east corner, and lifts seven tons to a height of 22ft. All the motions of this crane, which is shown in Fig. 8, namely, lifting, slewing, and racking in are effected hydraulically, the valves being placed on the riveter, so that one man can control both riveter and crane. It is made on Tweddell's system by Fielding and Platt, as is all the hydraulic machinery throughout the works, including, besides the riveting tools and their accessories a great number of cranes. The various riveters, both fixed and portable, we shall deal with in due course.

A hanging portable hydraulic riveter with very small gap, for use on furnace doors, claims attention on the score of its special suitability to the work in question. It can, by reason of its freedom to revolve on a gudgeon, rivet the Webb angular flanged rings as well as the ordinary. The gap is necessarily very small, in order that the machine may be admitted through the firedoor ring, as in Fig. 9.

The accumulator supplying all the hydraulic appliances throughout the establishment is situated just outside this shop. It has a 15ft. stroke, and is fitted with automatic stopping and starting gear.

The general erection of boilers is carried on in this first bay. Passing down it among boiler barrels, fireboxes, tanks, parts of tenders, &c., we have an opportunity of admiring the character of the workmanship, and noting that the edges of all plates are planed in accordance with the best locomotive practice; also of observing the accuracy with which the drilling is done. We will not go so far as to say that a drift is not used, but we certainly can say that we never saw this tool in requisition.

In the next bay—that in which our photograph on page 504 was taken—are the principal tools, some of which are worthy of mention. On our left is one of Buckton's angle iron shears, and further up the bay is a double-headed drilling machine—prominent on the foreground of the picture—by Craven, which is used for drilling fire-boxes, and a good deal of general work. The cross slide will admit work 9ft. 6in. wide, the spindle being adjustable 8ft. 3in. apart, taking 4ft. 9in. from floor line to the bottom of the spindles. There are two of these machines in use. Further up there is just visible in the picture a pair of rolls, about which we must again have something to say.

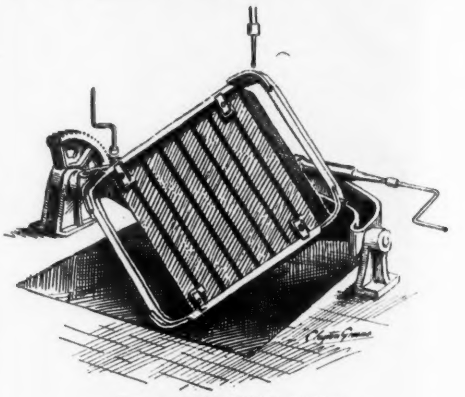

Fig. 13—TURNABOUT TABLE

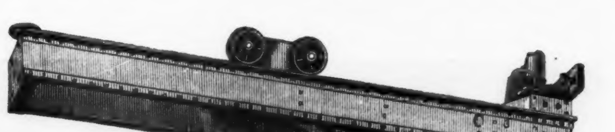

Fig. 8—HYDRAULIC CRANE ON TWEDDELL'S SYSTEM

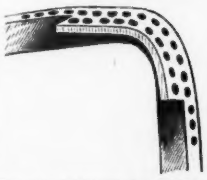

Fig. 14—CORNER OF FOUNDATION RING

They have been designed by Messrs. Sharp, Stewart, specially for cylindrical work, and there is a special arrangement for removing one of the bearings of the top roll to allow of the withdrawal of the plates when they have become cylindrical. This is clearly shown in Fig. 10. The rolls are arranged pyramidically, and take plates up to an inch in thickness and 9ft. in width. The two lower rolls, which are 11in. in diameter, are geared together and driven by spur-wheels, the top roll, 13½in. in diameter, being free and adjustable vertically. A clutch is provided to raise or lower one end alone, for conical rolling, the steps and bearings of the top roll having balls and sockets to allow of this movement. For cylindrical work one of the top roll bearings can be slid, by means of a hand-screw, on to a swinging frame, leaving the end of the roll unsupported. This frame, in order that it may be got clear of the roll plate when being withdrawn, is pivoted in such a way as to enable it to be turned temporarily into a horizontal position, the weight of the top roll being taken in the meantime by the adjustable carrier at the right-hand end.

Near is a useful boiler-drilling machine by Kendall and Gent, which we illustrate in Fig. 11. In these machines four drills can be advanced or withdrawn simultaneously through precisely the same distance no matter at what angles their spindles may be set, the rate of advance being at a suitable speed for drilling, while the return of all the drills is almost instantaneous; the two drills pointing truly to the centre of the boiler, having adjustment for varying their distance apart to suit the different diameters of shells and varying pitches of rivets. The drilling spindle has at the opposite end to the drill a square-threaded screw cut upon it, and upon this is mounted a circular nut. If the nut were revolved at the same speed as the spindle, no advance of the drill would be made. If, however, the number of revolutions of the nut be diminished by differential gearing, the drill can be advanced at any determined a speed. On the spindle is mounted also a sleeve with sliding key, which latter acts as driver of the gearing for the nut when the drill is advancing. The connection between the sleeve and the first driving pinion is so formed by a spring catch that it will drive the revolving nut when the spindle is running in one direction only. Hence, when the direction of rotation of the drill spindles is reversed the nuts remain at rest, and the spindles are withdrawn at a speed due to the full pitch of the screw. When the machine is in action, the uprights are rigidly bolted to the longitudinal bed carrying the table; and vertical slides on the face of each upright allow of the saddles being simultaneously raised and lowered by power, for different heights of rings or when drilling the butt seams. Each drilling saddle carries two heads, the spindles of which can be adjusted to any angle by right and left-hand screws, so as to point to the centre of a boiler of any diameter; and the centres can be adjusted apart to distances varying from 2in. to 5in., pitches below 2in. being drilled alternately. This is certainly an interesting machine, and especially noticeable for its rapidity; the best results being obtained by running the drills at as high a speed as 215 revolutions per minute, and advancing at the rate of $1\frac{7}{16}$in. per minute in $\frac{13}{16}$in. holes, four holes being drilled at the same time. With $\frac{15}{16}$in. holes the machine is capable of drilling $1\frac{7}{32}$in. per minute, the drills running at the rate of 185 revolutions per minute. The machine will take shells from 2ft. 6in. to 5ft. in diameter, and rings made from plates up to 7ft. wide.

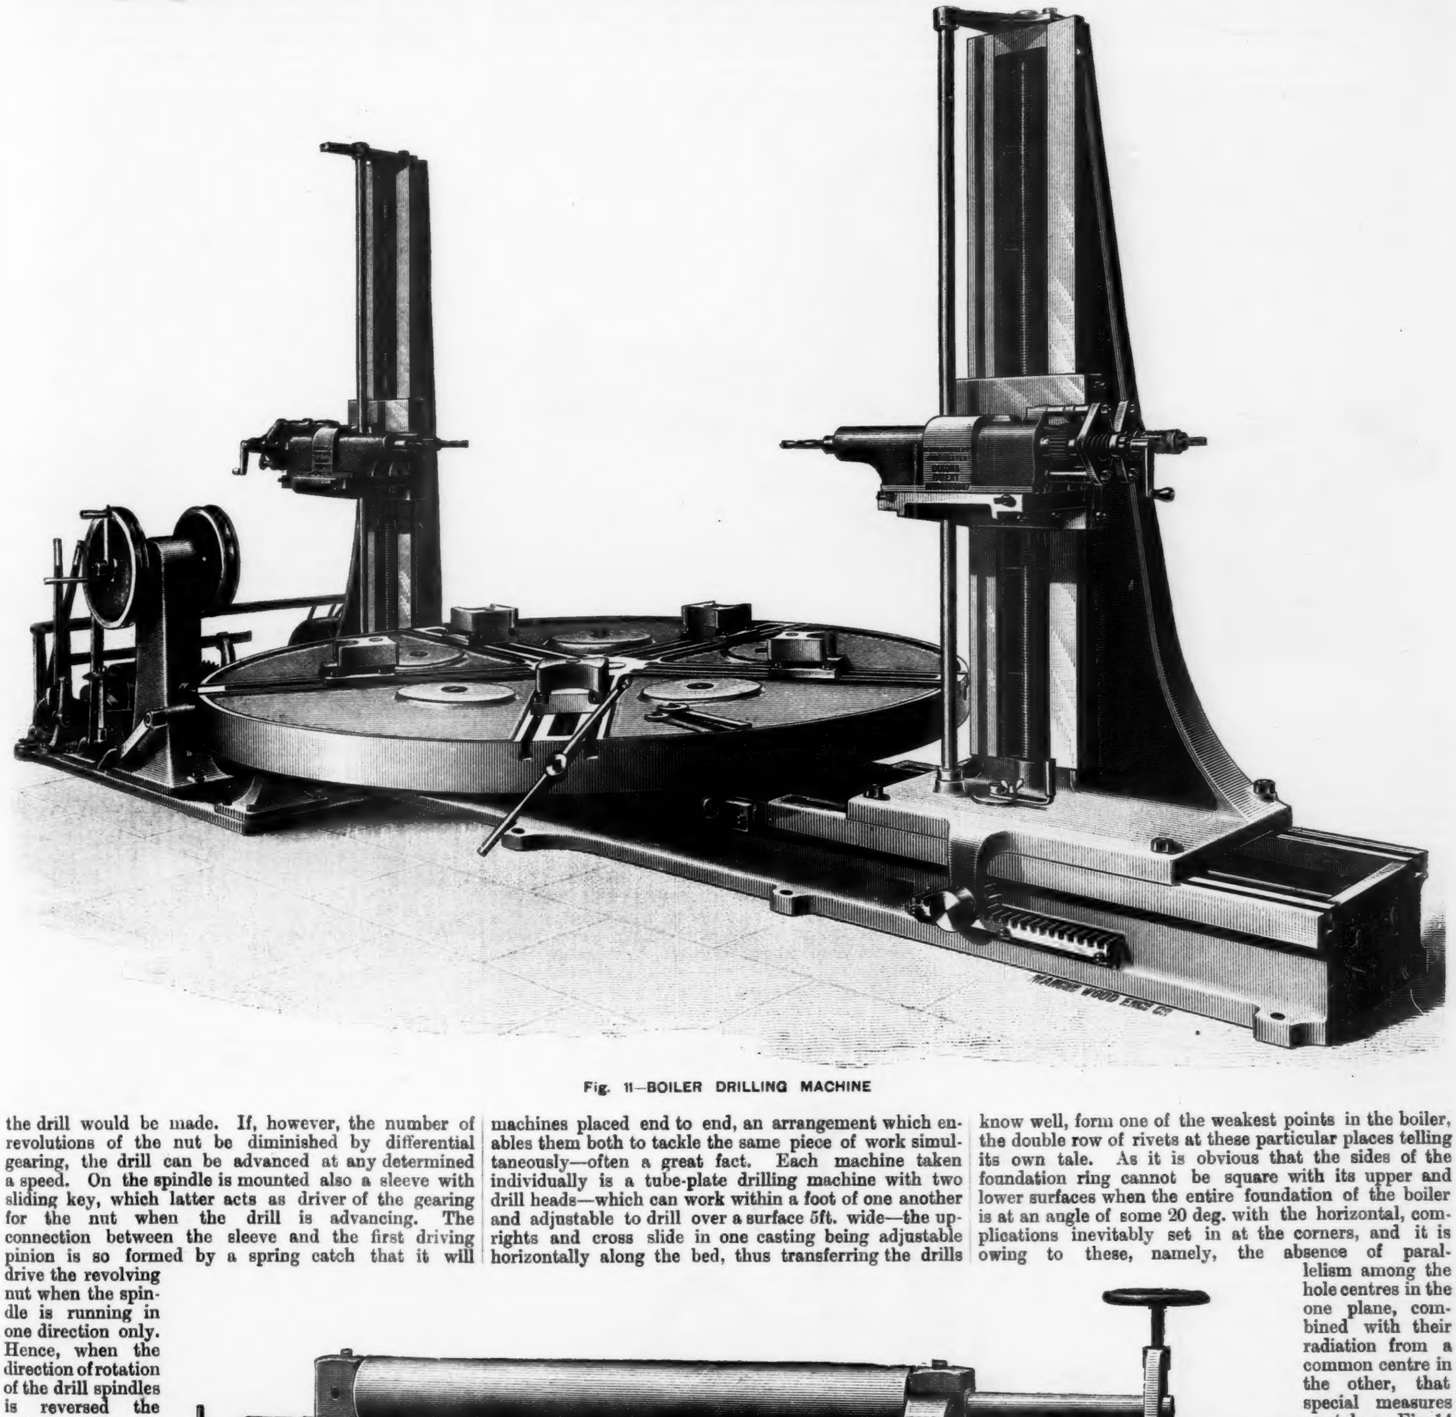

Fig. 11—BOILER DRILLING MACHINE

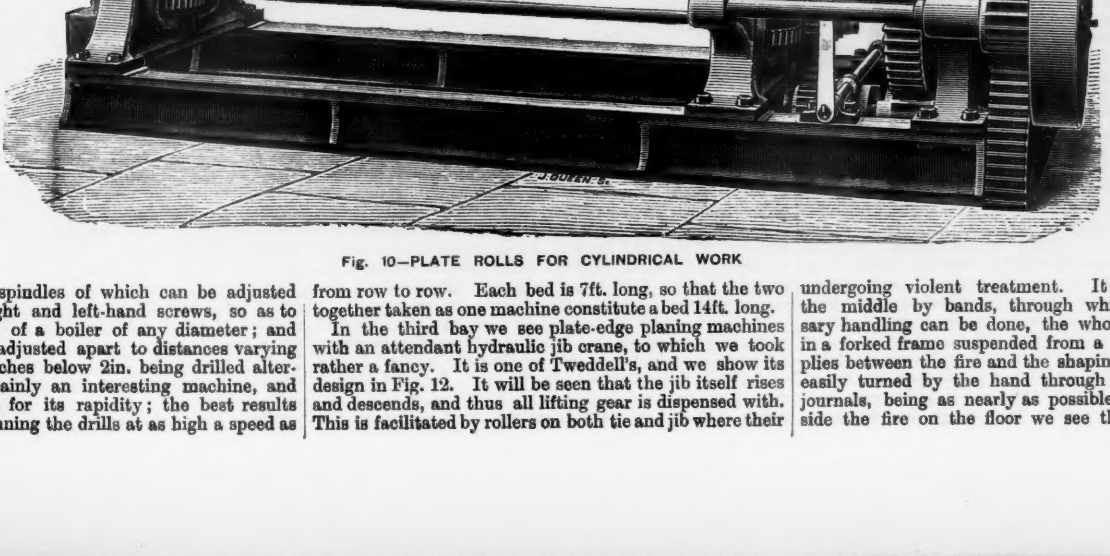

Fig. 10—PLATE ROLLS FOR CYLINDRICAL WORK

We have now come to the end—the far end according to Fig. 7—of this bay, and here we find what appears at first sight a heavy machine, but in reality consists of two machines placed end to end, an arrangement which enables them both to tackle the same piece of work simultaneously—often a great fact. Each machine taken individually is a tube-plate drilling machine with two drill heads—which can work within a foot of one another and adjustable to drill over a surface 5ft. wide—the uprights and cross slide in one casting being adjustable horizontally along the bed, thus transferring the drills from row to row. Each bed is 7ft. long, so that the two together taken as one machine constitute a bed 14ft. long.

In the third bay we see plate-edge planing machines with an attendant hydraulic jib crane, to which we took rather a fancy. It is one of Tweddell's, and we show its design in Fig. 12. It will be seen that the jib itself rises and descends, and thus all lifting gear is dispensed with. This is facilitated by rollers on both tie and jib where their stresses come on to the crane post. The vertical columns serve as guides for the cylinder, which is placed between them and forms part of the crane post. Further on are several more drilling machines—one having a turnabout table of a type which we do not remember having met with before. It is shown in the sketch, Fig. 13, with a foundation ring clamped to it for the purpose of drilling the rivet holes, which become a little troublesome at the corners owing to the nature of the ring. Fig. 14 shows one of the corners, which, as all locomotive engineers know well, form one of the weakest points in the boiler, the double row of rivets at these particular places telling its own tale. As it is obvious that the sides of the foundation ring cannot be square with its upper and lower surfaces when the entire foundation of the boiler is at an angle of some 20 deg. with the horizontal, complications inevitably set in at the corners, and it is owing to these, namely, the absence of parallelism among the hole centres in the one plane, combined with their radiation from a common centre in the other, that special measures are taken. Fig. 14 pretty well explains itself, the only thing which is hidden being the worm and wormwheel immediately at the back of the table, which turns the table proper in a plane at right angles to the plane of rotation of the carrying frame. This machine was made by Fairbairn, Naylor, and Co.

The remaining bay is the boiler smithy. We are attracted by a glowing dome undergoing violent treatment. It is gripped about the middle by bands, through which all the necessary handling can be done, the whole being journalled in a forked frame suspended from a jib overhead, which plies between the fire and the shaping block. It can be easily turned by the hand through extensions of the journals, being as nearly as possible balanced. Alongside the fire on the floor we see the set-plate, which represents for the time being the boiler shell. It is made fast to the ground, as shown in sketch, Fig. 15, and the set of the dome flange is being continually tried thereon. Those which we saw treated were for the Rhymney Railway locomotives, without the usual angle iron at the crown, the dome being flanged instead. This is rather a difficult piece of work, the actual flange being thicker than the dome plate in view of its having to carry studs. The thicker flanges are obtained in this case by utilising special "thick-edged" plates rolled by some of the best Yorkshire houses, their section being shaped as shown in cut. The plate is first welded into a cylinder, and the flange then formed by bending the plate inwards all round. There are a good many domes lying about, presenting various forms which are shown in Fig. 16, and is an instance showing how much superior a class of ability is needed in the employés of a firm conducting general locomotive work, and prepared to make locomotives to any design or pattern than is needed in a railway company's works, where the standard patterns are rarely departed from.

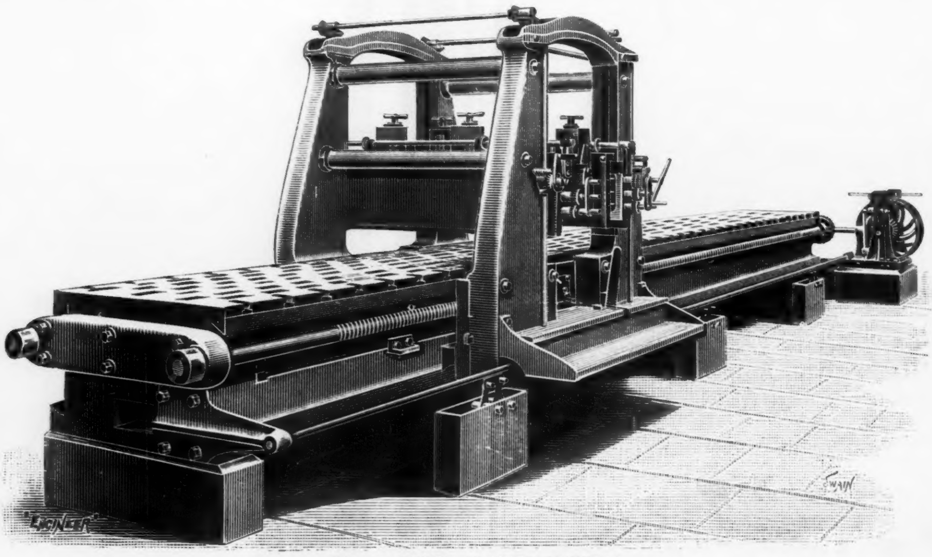

Fig. 31—FRAME PLANING MACHINE

The plate bending shed presents no very novel feature. The hydraulic plant, that is the flanging press, is of the usual type; also the "flangers." We will not, therefore, weary our readers with a description of methods of such universal adoption, but will here confine ourselves to an illustration of the quick way in which light splasher boxes are turned out, such as are fitted inside tenders, whose opposite wheels are closer together than are the opposite sides of the tank. It is the usual employment of male and female dies, as shown in Fig. 19. The finished article is shown below. Furnace fronts and tube-plates, &c., are flanged in the same machine, which is an ordinary Tweddell flanging press.

We now enter the extensive department in which the locomotive assumes definite shape, where all its parts at some period of their transformation receive treatment, and out of which the engine steams a living thing, ready for its trial run, complete in every sense but that of its final adornment of paint. This building consists of six bays, four of which approach 400ft. in length, the total width of all six being about 280ft. It comprises, as will be seen from the plan erecting, boiler mounting, frame, and heavy and light tool shops, which we shall proceed to deal with in the order just given. Fig. 20 gives a perspective view of the erecting shop as we enter it. Overhead are two travelling cranes, by Craven, of 30 tons capacity, driven by rope gearing. We may here briefly allude to the peculiarities of the crane-driving arrangement, which serves for the adjacent two bays as well as that in which we now stand. A two-cylinder wall engine, with cylinders 9½in. in diameter by 18in. stroke, is coupled direct to a countershaft running transversely across the three gables, from which the ropes of five cranes, capable of lifting in all 95 tons, take their motion.

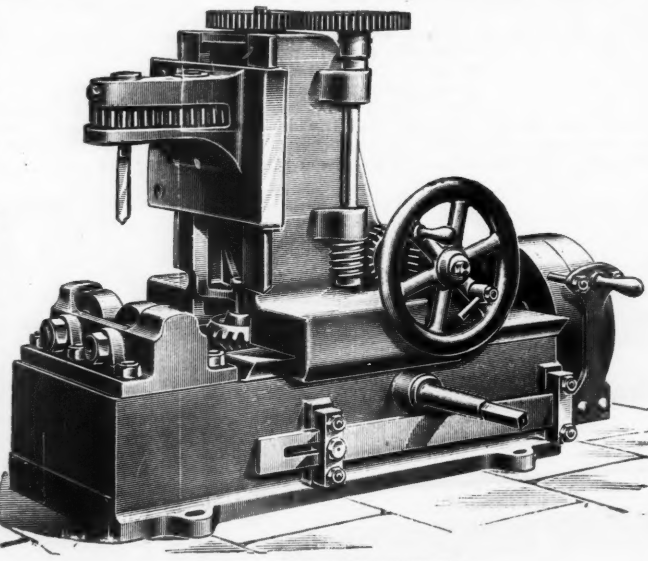

Fig. 30—TIRE DRILLING MACHINE

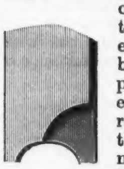
The driving ropes run 2000ft. per minute and pass from the countershaft partly round three grooved pulleys, on the crane headstock, from which the three motions necessary to the crane are taken. Besides these, hydraulic jib-cranes, situated at intervals along both sides of the shop, are very convenient; these are on the same principle as that of the rod type which we saw in the boiler shop, that is, with regard to the raising and lowering of the jib. We might now find ample pretext for devoting many pages to a treatise on the arts and mysteries of locomotive-erecting. But, to do this, two things are wanting, namely, space and something new to say. Even were the first secured, we could not guarantee the second, seeing that we have quite recently published an exhaustive series of articles on "The Construction of the Modern Locomotive." At Sharp Stewart's, ordinary practice is not departed from to any extent. We shall, therefore, confine ourselves in the main to describing what the place is like—leaving wider questions to articles of a different nature. At the vices, where the men are chiefly engaged in fitting and finishing axle-boxes, we were shown a special tender axle-box, which has been adopted by Mr. Jones for the Highland tenders, and which we endeavour to elucidate in Fig. 21. The object sought in this device is the quick withdrawal of the brass, only the removal of the front cover being required besides the usual lifting of the box. When the weight is thus taken off the brass, it remains behind on the axle, and with it the wrought iron block or distance piece, which lies on the top of the brass. This wrought iron block is slightly recessed into the top of the box itself, and so can only be withdrawn when the brass has fallen. The brass can then be lifted clear of the collar of the axle and taken out.

It is noticeable that the old horn-block is being superseded in the case of the Midland and Great Northern Joint engines by cast iron guides, with chilled cheeks, shown by A A in Fig. 22, the axle-box being case-hardened. We understand that the Midland Co. is alone in adopting this. Where the horn block is used, it is now almost invariably of cast steel. The appearance of these frames sets us thinking of the past—reminding us of the picture of the Sharp, Roberts' frame, which we reproduce in Fig. 23, to be seen in the earliest works on the locomotive. The form was originally designed to dispense with the use of long axle-box guides, which were necessary for the carrying wheels when the frame had no curvature—the frame in a sense accommodating itself to the axles. The design was considered then, so the books say, to unite strength with elegance, which latter qualification the other frames, such as Stevenson's and Bury's, were supposed to lack. This modern frame is obviously a survival of the old design. Another peculiarity which we noticed in these Midland and Great Northern Joint engines lies in their boiler lagging. The Midland Co. employ silicate cotton for this purpose exclusively.

We must pause a moment to look at a portable tool which appears more than usually convenient; this is a key-grooving machine, which we illustrate in Fig. 24. As might be at first surmised, the disc here does not revolve on a fixed centre. The crank-pin, therefore, does not rotate, but simply vibrates on the fixed centre at the other end of the link, which centre is mounted on an excrescence on the bed of the machine. It is obvious, therefore, that if the disc is caused to rotate its centre must reciprocate; consequently, the entire sliding headstock on which this disc is journalled reciprocates, the length of the travel being variable by means of the slot on the disc. The disc receives its motion from the pulley-shaft through elliptical gearing, to ensure uniformity in speed of transverse, all being contained inside the head. The driving pulley in the shop shafting is, of course, wide enough to allow the belt to traverse with the reciprocation of the tool head. The cutting is on the principle of the slot-drilling machine. The nature of the tool employed is shown in the accompanying cut.



If we now pass through the line of columns at our right hand, we enter the next bay, which is divided into two departments—viz., frame shop, where we now stand, and the boiler-mounting shop, which is at the far end. In the former—see Fig. 25—are seen engine, tender, and bogie frames, receiving such fittings as axle-box guides and brasses, stays, &c., this being their half-way house, so to speak, between the machines and the erecting shop. Among the tools here is a portable hydraulic riveter, which is most useful for light work in connection with the frames. We see it riveting the angle-irons on to cross-stretcher plates for both engine and tender, and small gussets, such as B B in Fig. 22, which represents the back end of one of the Midland and Great Northern Joint frames as we saw it in the erecting shop.

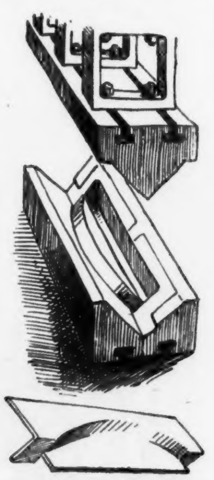


Fig. 19—Splasher Box Mould and Finished Article

A row of six of the firm's jib vertical drilling machines are evidently taking the overflow work from the frame-drilling machines in the next bay, which they do perfectly well, besides being useful for all sorts of heterogeneous work.

Passing up among the frames we once more find ourselves in boiler-land. Besides the addition of their mountings, the boilers here receive their fire-box stays, with the assistance of hanging portable rimer and tap rotators, of which we give a small sketch, Fig. 26. They can be seen in our view of the boiler-mounting shop, Fig. 27, where they are at work on one of the Midland and Great Northern Joint locomotives. This tool is doing the work at a great rate, and can be transferred from hole to hole with the utmost ease, a balance weight keeping the driving rope in tension under all conditions of working.

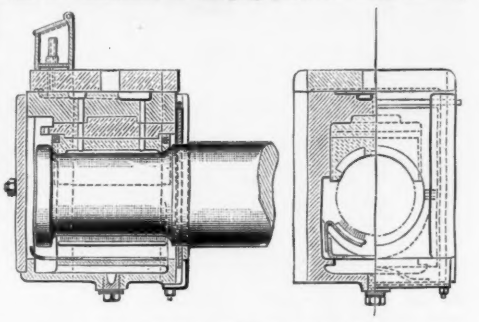

Fig. 21—SPECIAL TENDER AXLE-BOXES

We can now turn to what is perhaps the most interesting part of the works, namely, the heavy tool shop. It is so on account of the variety of machines which it contains and their special features.

The shop consists of the entire length of Bay No. 3, and, like the last, includes two departments, namely, that for general heavy work and the wheel department. We shall commence with the latter, it being the nearest. Figs. 28 and 29 are two views of the shop. In Fig. 28 we are looking up the shop, that is to the north-west—see plan—and in Fig. 29 to the south east. Proceeding upwards, therefore, the vertical wheel-boring machine on our left—see Fig. 28—first engages our attention. As can be seen from Fig. 28 this machine has two tables, one for driving wheels, the other for carrying wheels. The wheels, when bored, are transferred to the hydraulic wheel presses alongside. These cannot be seen in Fig. 28, being right in the left-hand corner. The lathes here seem to be mostly by Shanks and Whitworth. On the right are three large wheel lathes, about which we do not remember seeing any unusual features We observed, however, that the firm no longer turn their crank axles themselves, but buy them finished. Many makers of crank axle forgings have plant for turning them now. It is purely a question of convenience. Further up on the left is a milling machine, originally designed by Craven Bros., for milling crank bosses, with an ordinary milling cutter, 4in. diameter, having coarse-pitched teeth; but in consequence of the growing disuse

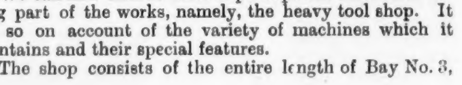

Fig. 23—OLD SHARP-ROBERTS' FRAME

of wrought iron wheels, the machine has lost much of its importance, the cast steel wheels not requiring any treatment in this respect. The machine is, nevertheless, still found useful, particularly for circular work, the table being adjustable in order that boss work of any kind can be placed central with the circular motion; there being also compound self-acting slides to mill in a straight line, which are, of course, useful in rounding-off connecting or coupling-rod heads. Crossing the bogie railway we come to two tire-drilling machines on the right, the firm's own make. We illustrate one of these in Fig. 30. This machine is drilling holes 1in. in diameter and 3in. deep in the tires of wheels from the inside of the rim, the drilling head being carried on vertical vees in a headstock capable of horizontal adjustment. Opposite to this machine is a quartering lathe by Whitworth for boring crank-pin bosses at right angles to one another—or in other words, at quarter centres—also for turning crank pins. The machine is enabled to bore conically by means of a short boring bar carrying an inclined slide, along which the tool is fed by means of a pair of bevel wheels, the adjustable spindles of the machine having self-acting feeds for boring, turning, or screwing. It is a heavily-built machine, and will take wheels up to 8ft. in diameter, on axles over 8ft. long, with crank throws as long as 2ft. 2in. Two wheel-slotting machines—Webb's patent, which can just be seen under a pile of crank-axles—have fallen into almost entire disuse, owing to the cast steel wheel centres not requiring this treatment.

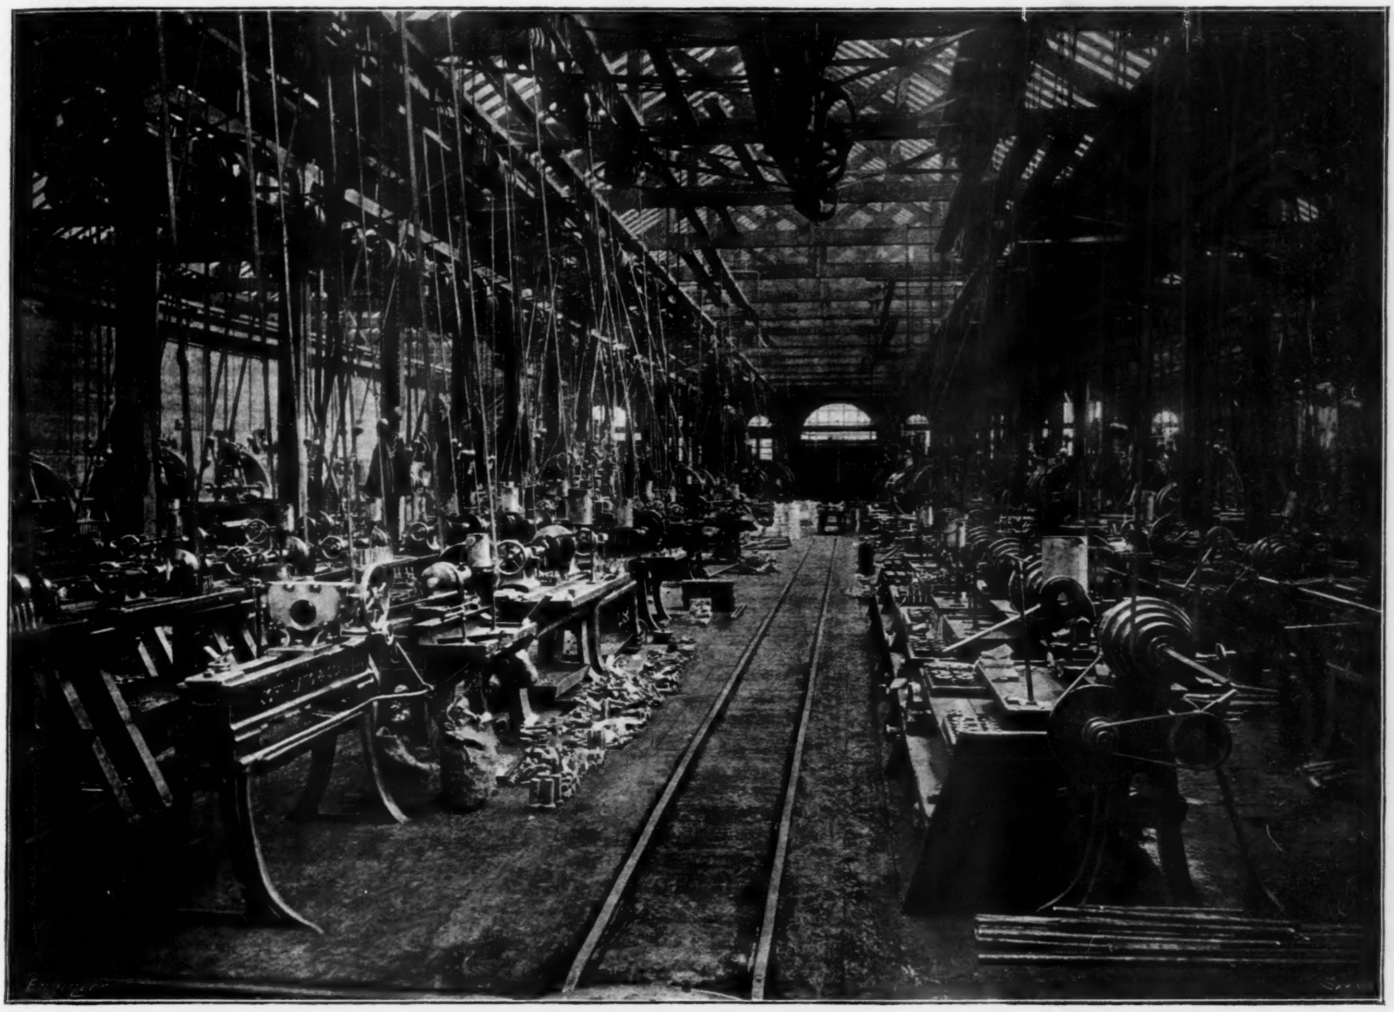

Fig. 37—LIGHT TOOL SHOP, BAY NO. 5

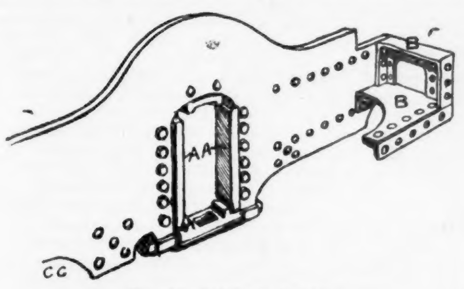

Fig. 22—EMBRYO FRAME

With respect to crank pins, it is noticeable that there is some difference of opinion with regard to the method of securing them to the wheels. For instance, we observe that the Joint Midland engines have pins of uniform diameter where they pass through the wheel, with a shoulder, while the Highland engines have the usual conical pins. The Midland Railway Co. is the only company we know of in this country which prefers parallel sides on crank-pin seatings. They are forced in by hydraulic pressure and riveted over. Another lathe here, by Whitworth, is turning the bosses of wheels, for which purpose it has a special gap, admitting wheels up to 8ft. 4in. diameter. The wheel to be bossed is placed on a mandrel which revolves in bearings, the lathe centres taking the end thrust occasioned by the tool in cutting, the mandrel being driven from the face-plate by a carrier. There are four rests, which are all under control from whichever side of the lathe the workman chooses.

Now we come to the large machines specially designed for dealing with frames. The first of these is on our right, and is a frame-drilling machine by Shepherd, Hill, and Co., having three drilling heads, tackling sometimes over six frames at once, one above the other. The table measures 36ft. by 5ft. Opposite to this machine is a duplex frame-planing machine by Craven, a splendid tool, shown in Fig. 31. It will plane work 30ft. long by 5ft. wide, admitting 2ft. under the cross slide. The frame, consisting of four standards, is actuated by two screws, one at each side of the bed, geared together by mitre-wheels, each pair of standards carrying a cross slide with self-acting tool boxes for vertical, horizontal, and angular cuts, each of which boxes may carry several tools. When the standards are travelling one set of tools is raised from the work, the other set coming into play on the reversal of the direction of travel. Both time and space are thus saved, the former by uninterrupted cutting, and the latter by the avoidance of a table traversing a distance double its length. The entire machine weighs thirty-three tons. Opposite is a huge machine, which we do not illustrate, for the excellent reason that we have already done so in a previous issue. It is a frame-slotting machine by Craven, and will be found fully illustrated and described in our issue of November 23rd last. It is also discernible in the view of this end of Bay No. 3, given in Fig. 29 on P. Its bed is 36ft. long, admitting work 5ft. in width. The stroke of the tool head is adjustable to 15in.

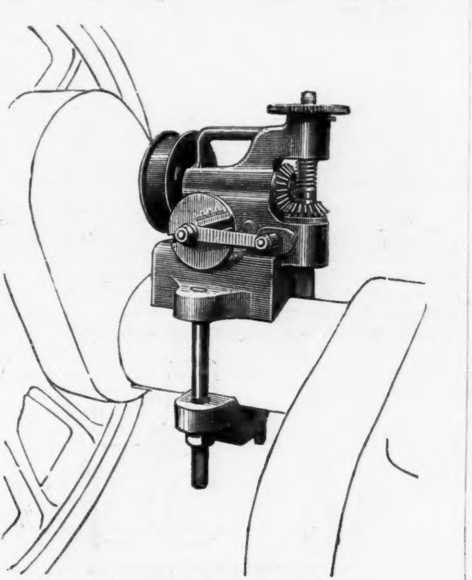

Fig. 24—PORTABLE KEYWAY CUTTER

On the left-hand—opposite Craven's slotter—is a number of small drilling machines, some of the firm's own make, others by Harvey, of Glasgow; also a brake lathe by Hetherington, Manchester. Further down on the right are four planing machines, including a special machine by Craven, designed to plane both ends of connecting or coupling rods simultaneously, suited also to slide bars, axle-boxes, or any motion work where there is repetition. Its difference from ordinary machines lies in the fact that the table travels in both directions at the same speed, there being two pairs of standards, and therefore two cross slides. The table has adjustable stops for various strokes, and takes work up to 10ft. in length and 4ft. in width, admitting 2ft. under the cross slides.

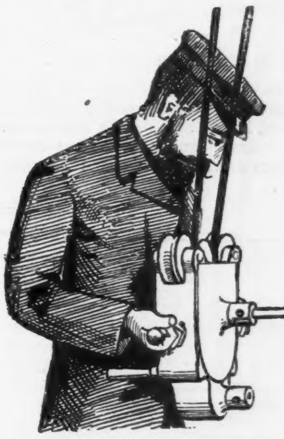

Fig 26—RIMING AND TAPPING TOOL

The three other planing machines here are all by Sharp, Stewart, and Co., and have the diagonal worm shaft for driving the table, which is perhaps the chief characteristic of their machines. This is made clear by the diagram—Fig. 32—the object being a straight thrust from the surface of the worm-teeth in the direction of the resistance. The worm gears into a machine-cut rack, and is running constantly in an oil well. We ought not to pass these planing machines by without an allusion to the firm's patent feed motion—Robinson and Oldfield's patent. It has more than one feature to recommend it, and should therefore be known. We must here, having due regard for the patent obtained for this device, confine ourselves to stating that there is a cam enclosed in a box which is caused to turn at the end of the return stroke so as to put on the feed then, the travel of the table necessary to do this being no larger than that demanded by the ordinary feed motion, and there is no drag of the tool over the work during the feeding.

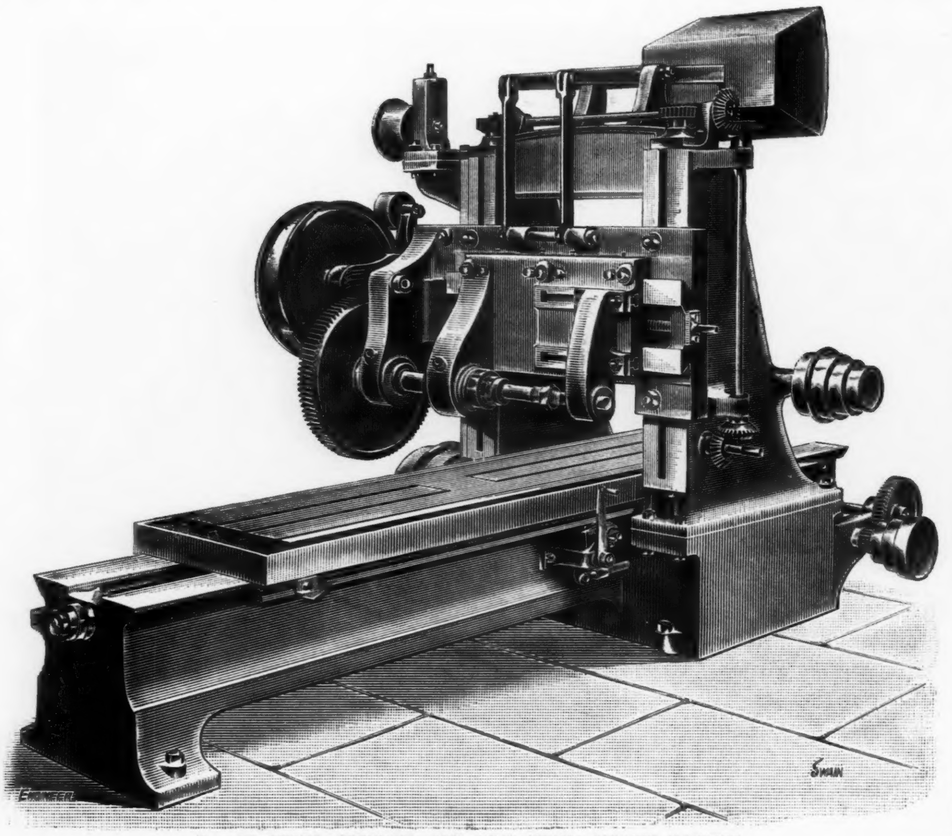

Fig. 35—SHARP, STEWART, AND CO.'S HEAVY MILLING MACHINE

Passing by a cluster of machines of various kinds, we cross over into Bay No. 4, and shape a south-easterly course. This is the light tool shop, as shown in Fig. 33. It must be understood that this photograph is taken looking in the opposite direction to that in which we are now moving; therefore what is seen in the foreground we shall not deal with—till we get there. The travelling crane, which runs on one rail the complete length of the shop, is by Craven. We give a sketch of it in Fig. 34. The crane is guided at the top by two light rolled steel girders carried by brackets attached to the roof principals. The bottom carriage and crane are carried by two double-flanged travelling wheels. The jib can swing right round. All the motions for lifting, lowering, and traversing are derived from an endless rope running the length of the shop, which, guided by the jockey wheels at the top, drives a vertical shaft down the centre post. This shaft has a pulley near the top, which drives by an open and cross belting the lifting gear, and another pulley near the bottom which drives the travelling wheels in the same way. These are all under the control of the crane man by hand wheels. This crane will lift five tons. The plant here consists, firstly, of three cold saws by Butterfield, and several most useful grinding tools. One of these, by Craven Brothers, is especially worthy of mention. When we saw it it was at work on case-hardened driving-wheel axle-box cheeks, but is useful for flat surfaces of any kind, such as slide bars, slide valves, &c. Its feature consists in the transverse reciprocation of the wheel while the work is passing, and as the stroke of the table and transverse stroke of the wheel do not synchronise, it follows that as the work proceeds the wheel engages with the entire surface to be treated in both longitudinal and transverse senses, the resultant path of the tool over the work being semicircular.

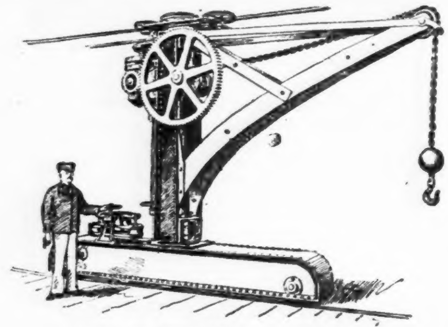

Fig. 34—TRAVELLING JIB CRANE

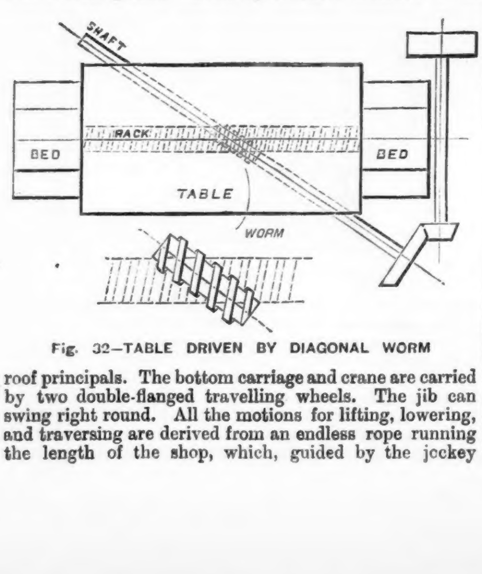

Fig. 32—TABLE DRIVEN BY DIAGONAL WORM

These driving-wheel axle-boxes are ground also on their inner sides, and are expeditiously done, two at a time on a reciprocating table, two emery wheels engaging alternately, one with the lower the other with the upper portions of their respective axle-boxes. At the end of each stroke a stop engages with a cam, which throws the belt over and reverses the motion in the ordinary way.

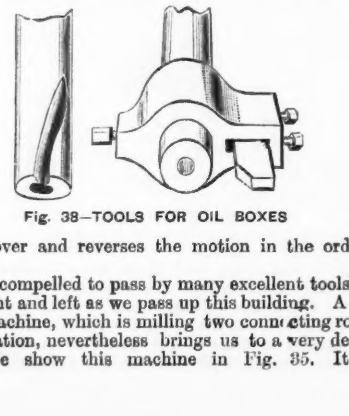

Fig. 38—TOOLS FOR OIL BOXES

We are compelled to pass by many excellent tools both to our right and left as we pass up this building. A large milling machine, which is milling two connecting rods at one operation, nevertheless brings us to a very decided stop. We show this machine in Fig. 35. It has been specially designed for forged steel work, and is therefore of a massive character. Some idea of its size may be conveyed by the fact that it admits work as wide as 3ft. milling a length of 10ft., and taking cutters up to 1ft. in diameter, and the extreme distance from top of table to centre of spindle is 2ft. 8in. The spindle is 5¼in. in diameter at front end, and has a removable outer bearing necessary for taking out the cutter, mandrils, &c. The table is driven by a screw, and has automatic knocking-off motion at any part of its stroke. A pump is attached, which throws lubricant on the cutter—an indispensable item. This is another machine which is "home-made" only, of course, in the literal sense of the phrase.

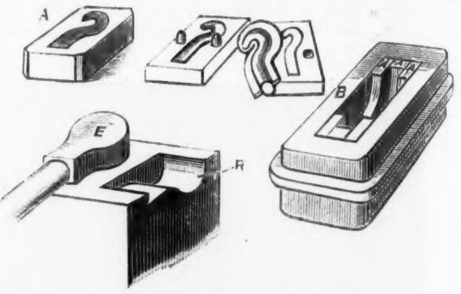

Fig. 40—MOULDS AND DIE BLOCK

Opposite is an axle lathe by Thos. Shanks and Co., Johnstone, fitted with breast slides at the front of the bed, on which are fitted the saddles which carry the slide rest. This enables the turning tools to completely traverse the shortest journal without obstruction. The centres do not overhang the loose headstock, and are very sturdy to resist the pressure of the cut. One of the loose headstocks, as in many axle lathes, is balanced, and can be swung out of the way, thus facilitating the withdrawal of the axle. The bed of this machine is 12ft. long and admits axles up to 8ft. long, the centres being 13in. above the bed. We were told that this machine will easily turn the two wheel-seats, two journals, and the two collars of an ordinary axle in nine hours.

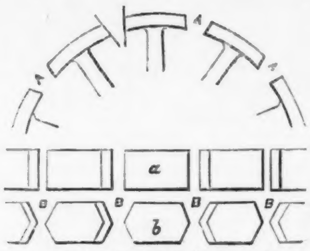

Fig. 41—WROUGHT IRON WHEEL FORGING

Beyond are a number of planing machines of various shapes and sizes, some by Hulse; another duplex planing machine, by Craven, similar to that already spoken of in the heavy tool shop; an axle-box planing machine, by Shanks, which is well worth mention on the score of its convenience. It carries eight tool slides, or four on each of two cross slides, which are supported by common standards. It is a squat-looking affair, only admitting 1ft. 6in. below the slide, and has, generally, regular bull-dog qualities. The table, which measures 10ft. by 4ft. 6in., is driven by a screw of large diameter and can plane twenty-four axle-boxes at once, *i.e.*, four rows of three boxes at each end. Each tool slide is self-acting and independent—horizontally and vertically.

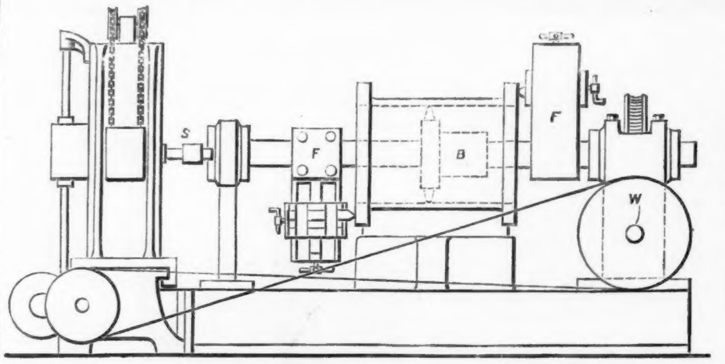

Fig. 36—CYLINDER BORING AND FACING MACHINE

A collection of horizontal boring machines give us an idea of the amount of work in hand, showing as they do the large number of cylinders undergoing a refining process, so to speak. One of these machines which is facing both ends of a cylinder at once, having already bored it, we illustrate in Fig. 36, as we consider it a most useful combination. It is by Craven Brothers, and has a boring bar 7in. diameter centred 2ft. from the table. The bar carries three tool heads, two F F being facing arms. The boring head B carries three tools. There is, besides, a boring spindle adjustable vertically and horizontally in a cast-iron standard, which is used for boring valve spindle holes or drilling ends of cylinders when cast in one with the barrel. The bar is driven by worm gearing at W.

The second light tool shop—of which we give a view from the north-west end, Fig. 37, p. 517—contains a collection of small machines of the stud lathe, and nut-facing order; also some brass-milling and nut-tapping machines by the ubiquitous Craven Brothers—what might be termed the *profanum vulgus* of machine tools. Two double spindle vertical drilling machines, bolted back to back on the shop columns, each consisting of a slide carrying two headstocks with a table below, are doing some interesting work on connecting and coupling rods, both ends of which are being drilled at the same time, a template bar being always used, which is a great safeguard against mistakes. This template is nothing much to look at—consisting merely of a wrought iron bar of something like 2in. by 3in. section—through which holes are carefully drilled to fit the drilling spindles at various distances apart. One bar will do for quite a number of different rods, and ensures great exactness when a large number of rods are centred alike. But what interested us most in connection with these machines, which are by G. and A. Harvey, Glasgow, was the method of drilling out oil cups in the heads of coupling or connecting rods. The drill used is of a special annular form, shown in Fig. 38. The hollow in the centre allows material to remain and form the feeding tube of the oil cup.

It will be seen that here again a difference of opinion is evident with regard to the shape of these oil-boxes, not so much with regard to the question of fitting a separate box as to the way in which the box, which is forged solid with the rod, should be finished.

Some rods, for instance, have a square box milled out, the cover being a separate piece, which is amalgamated with the sides by careful fitting and riveting over — others have the corners rounded off merely. Fig. 38 shows the form of tool employed for doing so. It is amusing, *en passant*, to watch the manipulation of the larger of the two quadruple tapping machines before alluded to. The hand levers which are fitted are clearly something more than their name suggests. They are levers of the second order, and in tapping nuts of, say, 1in. or 1¼in. it is vanity to suppose that this lever is to be used as a hand lever; far from it, it must be a body lever if that tap is to get started. So the operator thinks at all events, for he throws himself prone on to the handle feet off the ground, and there balances himself until the tap is started.

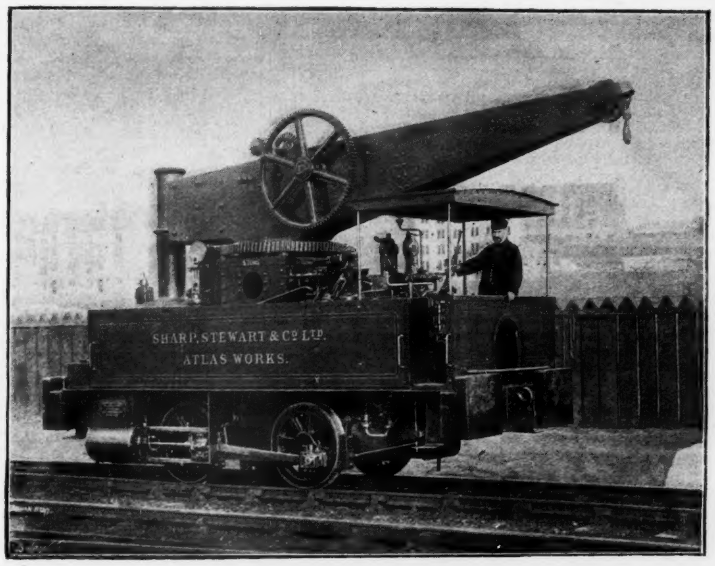

Fig. 44—WORKS' CRANE LOCOMOTIVE

We will not detain our visitor in the grinding or brass-finishing shops, nor in the store, where one merely sees the usual plant, but pass straight into the smithy, where we are immediately struck by its extent and the number of steam hammers it contains. The number of fires cannot be under forty-five, exclusive of the large furnaces which are eleven in number in a row on the south-west side of the shop, the largest measuring 12ft. by 7ft. As in all well-conducted establishments, the waste products from the large furnaces are utilised to supply steam for the hammers. Two locomotive boilers are used for this purpose fixed over the furnaces.

The hammers are by various makers, the largest, shown in Fig. 39 with quite a vista of hammers behind it, being by the late firm of Glen and Ross—now R. G. Ross and Son — Glasgow, and weighs four tons. This hammer is made under patents which Mr. W. Rigby, of Parkhead Forge, Glasgow, took out in 1854. They apply more particularly to the stuffing-box and frame than to the valve. Only one hammer was made by Mr. Rigby himself, who transferred the whole of his rights to Messrs. Glen and Ross, and probably made a very good thing out of it. These hammers have a peculiar feature which Mr. Ross added in the shape of an equilibrium piston valve, which effected quite a revolution in the mode of operation, as previously the cumbrous valve gear employed had been sluggish.

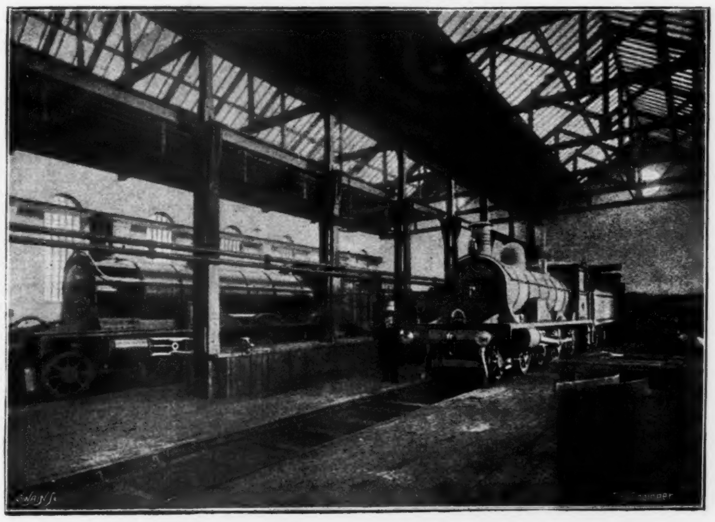

Fig. 45—PAINT SHOP

The principle of this valve is to take the steam from the lower side of the piston, after it has raised the hammer, and to utilise it on the upper side. Later a valve was added, whereby full pressure of steam could be admitted on the upper side of the piston, thus adding to rapidity of action and force of blow. The cylinder of this hammer is 29in. in diameter, with a fall or stroke of 5ft. The total height is 20ft. and the span 13ft. We had an opportunity of seeing this hammer doing some violent work on coupling cranks. Blocks of metal built up by the double faggoting process are brought under the hammer and driven into a recess, the shape of the web, in a cast iron block, reinforced by wrought iron bands, and is thus moulded into the required form. The overflow metal, or "fin," can be got rid of by forcing the metal out of the recess by means of wedges applied below, inserting another pattern-piece, dropping the metal into it with the "fin" resting on its upper surface, and placing a dummy crank web above the red hot crank web, which when struck by the tup drives the web through before it, and the "fin" takes a lasting farewell. In the same operation the metal is forced out to leave the pin and axle seatings, and the web is in about five minutes turned out a complete forging, the whole being done in one heat. This mould system is applied wherever possible, and is exceedingly quick, being of course especially valuable where a large number of forgings, identically alike, are required.

Take drag-hooks, as an example: these are, to begin with, forged into something very faintly resembling a hook, and quickly driven through a cast-iron pattern, something like A in Fig. 40. Then each is ready for the moulds B B in Fig. 40, from which it emerges, as shown, with the "fin" only remaining to be treated, which is quickly removed in the same manner as that mentioned in speaking of coupling cranks. We were shown an immense variety of these moulds, all displaying much ingenuity in their design. We cannot, however, afford space for more than one type. This is that shown in Fig. 40, which is used for the smaller sheaves of excentric pulleys, which are in most cases of wrought iron. The box B serves for many different sizes—by changing the pieces A, A, A, whose sides form the walls of the mould—the box B simply holding them together. This we think most ingenious—and commendable to all to whom a saving of time and labour is an object.

All hangers, brackets, details of motion work, &c., anything with a head of any shape are forged on the principle shown in Fig. 40, which is of course largely used, but we give this one illustration of it, as it is quite possible that some of our readers may not know of it. We are not writing solely for locomotive *savants*. E is to be an ordinary double eye. By alternately turning it over first on its face and then on its side in the recess R, while the tup comes down between every turn; the head is finished quickly and absolutely accurately. There can be no mistake about it. This principle can be carried out to any extent, a fact which Messrs. Sharp, Stewart, and Co. certainly recognise.

With regard to the steam hammers, we may here state that there are seven hammers by Glen and Ross of 4 tons, 2 tons, 12½ cwt., 6 cwt., and two of 5 cwt., and a horizontal double-ended "veeing" hammer. This last we should weep over, as it is now nothing more than a monument to the memory of wrought-iron wheels. It is useful now and then, but its glory has departed. To those who are not moved by this spectacle, we would point out that the process of "veeing" was, a few years ago, universally adopted for welding the rims of locomotive and other wheels after the arms had been welded at the centre. Fig. 41 shows what we mean, the spaces A, A, A, denoting where the V-pieces are to go. But we must here inform the reader that the term "veeing" did not arise from the fact that the pieces inserted at B, B, B, were shaped as V in the elevation, but because the older method was to fit in dovetailed pieces, as in *b*, below, the origin of the "vee" arising from the spaces B, B, B, being the shape of that letter.

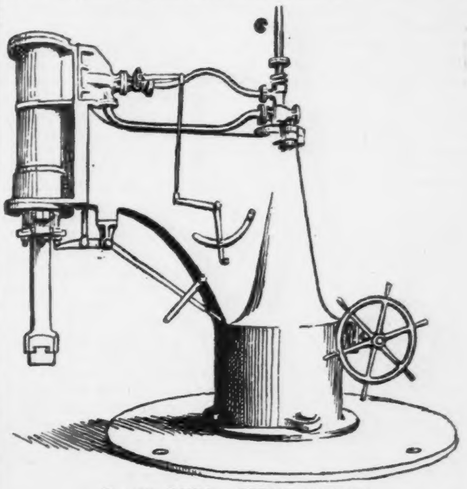

Fig. 42—RADIAL STEAM HAMMER

There are five hammers, by Harvey, Glasgow, of weights weighing between 12 cwt. and 5 cwt., two of Massey's varying 30 cwt. and 20 cwt., and a radial hammer, by Davis and Primrose. This is another relic of the past. Fig. 42 shows what it is like. The cylinder is mounted on a radial arm, which is free to revolve round a central post, the turning movement being controlled by a large star wheel. A most useful hammer this has been in its day. Its peculiarity lies in its capability of dealing with five or six anvils placed round it at once. Thus for the "scarfing" and "dabbing in" processes in wrought iron wheel work, the forging can be quickly transferred from die to die, the hammer following it, the hot forging being laid on each die in succession, thus undergoing a transformation. Usually a spoke can be completed as in Fig. 43 in one heat. But of course, for general die work, a good deal depends on the nature of the forging and the number of dies it has to pass through. Since, however, cast steel wheels have come so much into vogue, the radial properties of this hammer are rarely required.

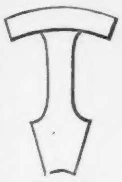

Fig. 43

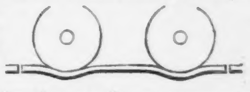
The iron and brass foundries are well equipped, but need not keep us. Readers can guess pretty well what they are like. All power is supplied by vertical wall engines, by J. Copeland and Co., Glasgow, placed outside the buildings, steam being generated by four boilers, by Messrs. Penman and Co., Glasgow.

These engines by Copeland formed subject for discussion in D. Kinnear Clark's work on the steam engine, as perhaps some of our readers know. Their peculiarity consists in their direct connection to the lines of shafting—the lengths of which vary from 180ft. to 80ft.

The crank shafts, and therefore the shafting, are 13¼ft. above the ground—the frame being rectangular, carrying the cylinder at the lower end. The shaft passes through the wall unconnected with any wall box. The cylinder is 16in. in diameter by 20in. stroke. The frame plate is bedded on oak and fastened to the wall with ten 1½in. bolts and cast iron wall plates of T section.

Fig. 44 shows a fussy individual, whose functions are of a most indispensable kind. As can be seen from the plan—Fig. 4—there are few places into which he cannot poke his nose, so to speak. He does hauling and shunting duties, and fetching and carrying of all kinds; a sort of works orderly. Messrs. A. Barclay and Son, Kilmarnock, supplied this engine. A fitting wind-up of the locomotive department is in the paint shop—Fig. 45—where two imposing Highland engines are being decently clad before being sent forth to cold and mountainous regions—and very beautiful clothing it is. This little picture—Fig. 45—perhaps will give the reader a better idea, at first glance, of the size of these engines than perhaps even our four-page supplement conveys.

The works are also intersected by a bogie tramway system. The turntables used in connection with these are of a sweetly simple description. Their charm lies in their ability to take the bogie without being adjusted to suit the lines. This is because they themselves have no lines or grooves—the wheels of the bogie simply falling into the corrugation as in the accompanying sectional diagram. One of these tables can be seen in the foreground of the light tool shop, Fig. 37.



The photographs we reproduce in connection with this article, were taken expressly for us by Messrs. T. R. Annan and Sons, of Sauchiehall-street, Glasgow.

We much regret that want of space compels us to hold over a number of illustrations of locomotives, representing Messrs. Sharp, Stewart, and Co.'s work both in the past and in the present. These, with an account of the machine tool department, which is also crowded out, we hope to deal with in a subsequent issue. We must here, however, take the opportunity of thanking all those who so kindly afforded our representative every facility, particularly Mr. J. F. Robinson, managing director, and Mr. John Sharp, jun., whose assistance we have highly valued.

## THE NIAGARA HALL ICE RINK.

Few of the most attractive of modern entertainments on the large scale, including the large theatres, would possess that attractiveness without the energising aid of the engineer. In some cases it would almost seem a degradation of the art of the engineer to employ it on such trivial or frivolous matters, but perhaps it is not more so than with the highest of the older arts, whose greatest aims are entertainment, more or less intelligent. At Paris there was the great tower of nearly a thousand feet in height, with lifts which taxed the ingenuity of the mechanician, there were the electrically illuminated fountains, the great wheel at Chicago, and others on which engineering skill and much energy and money were spent, and with one object, namely, to amuse and to make profitable employment for iron, steel, and brains, from the money people are willing to spend in being entertained by something which is not their work.

At Westminster the Niagara panorama has given way to a great rink, which will soon be completed, and provide a sheet of hard ice of about 112ft. in diameter, providing room for several hundred skaters at one time. The system upon which the rink is being constructed and equipped, namely, Uensold's, is a new one, and comprises several novel features. Hitherto the several ice rinks which have been made, including that which is so popular in Paris, have been constructed with concrete or other rigid floors for the ice sheet; in one of the first it was a cast iron tank floor. These floors are both rigid and costly, and the sheet of ice is costly to maintain, because of the heat conducted to it by these floors. The new floor is of wood plank laid upon iron joists, not too close together, and forming the roof or ceiling of a cold storage place below. Considerable flexibility in the floor is thus obtained, which is felt by those on the ice it supports, and as the ice sheet will be only about 5in. in thickness, it will in considerable degree behave like a sheet of natural ice. The boards are laid so as to be free to expand and contract, the joints being caulked and filled. The whole floor is covered with pipes of 2in. diameter and ⅛in. thick, arranged so that part or all may receive a full or partial supply of brine from the main, which is about 12in. in diameter. A total of about 30,000ft. of piping is now on the floor. The brine is cooled by three small size De La Vergne ammonia refrigerators, made by Messrs. Louis Sterne and Co., each capable of making 12 tons of ice per day, and when the ice is once formed one of these machines will generally be sufficient to maintain its low temperature and to provide for re-making the surface. The three refrigerators will be required to make the first ice sheet, and as the formation of this sheet will involve the making of about 260 tons of ice, the operation will take several days. Once the sheet is formed, about eight tons will have to be re-made per day to counteract the losses by wear and evaporation.

The refrigerators will be supplied with steam from two locomotive boilers by Messrs. Davey, Paxman, and Co., each capable of supplying 75 indicated horse-power to the engines of the refrigerators. The remainder of the refrigerator plant will be employed in maintaining the low temperature of a cold store of 60,000 cubic feet capacity below the rink and for making ice, the plant being capable of employment as may be most required either for the cold store, the rink, or for ice-making, or for all of these together.

The Niagara building was handed over to the builders for the modifications on the 24th of October, and it is expected that the formal opening of the rink will take place on the 5th of January next. There was a great quantity of material in the centre of the hall, which, as well as the material filling the space required for the cold store, had to be moved, and the progress has been so rapid that the whole of this has been done and the rink floor completed. The arrangements for heating the promenade of 14ft. in width which surrounds the rink, are also nearly completed. This promenade is separated from the rink by a strong iron rail about 3ft. high capped with wood, and from this hangs a blanket all round just touching the ice. Within this blanket the temperature will vary from 32 deg. near the ice to something more than that a little distance above, but outside this blanket in the promenade the temperature will be maintained at about 60 deg. There is also an upper promenade above that already mentioned. Messrs. Bramwell and Harris, MM. Inst. C.E., are the engineers for the whole of the works. The architectural work has been carried out from the designs of Messrs. Carslake and Mortimer. The rink is the property of the Niagara Hall Company, of which Mr. Hwfa Williams is chairman, the capital being only £42,500. The system of construction is similar to that of the Munich Rink, constructed by Mr. Uensold, but with several important improvements in details, and the experience with this has determined its adoption here.

---

The Preservation of the Propeller Shafts of Steamers: A Successful Invention. — It is now about two years since the first of the propeller shafts fitted with the arrangement devised by Mr. Mudd, of Hartlepool, for preventing their destruction by galvanic action and corrosion were sent to sea, and they are now rapidly coming in for examination. We are able to say that the device has so far proved entirely and absolutely successful in every respect, the shafts on examination having no trace whatever of galvanic action or corrosion, nor of the defects and decay that formerly so extensively resulted from these causes. As instances, we may mention the s.s. Guernsey, whose shaft has been running at sea for eighteen months since it was fitted with the preserver. This vessel had her tail shaft drawn at a dry dock in the Tyne recently, and the preserver pulled loose from its attachment to the shaft, when it was found not only that the shaft had been entirely preserved, but that the rubber sleeve itself had taken no harm and was capable of being cemented down again for a further period at sea. The s.s. Zanzibar, whose shaft was drawn at a dry dock in Cardiff, the manager of which writes saying he found it in perfect order, the sleeve having adhered splendidly to the shaft and retained its elasticity, forming a really good preservative, no corrosion whatever having taken place. The s.s. Elmville, which has during the present week been dry-docked at West Hartlepool, had her tail shaft drawn and examined after having been twenty months at sea, when exactly the same result was found. That is to say, the sleeve itself was in perfectly flexible and good condition, and when turned back from its attachment to the shaft, the shaft and the ends of the brass liners were found in the same perfect condition in which they left the lathe when new, having taken no harm whatever during the twenty months' work. The shaft was re-cemented and the preserver put down in its place again for continued use at sea. The best qualities of rubber retain their natural elasticity indefinitely when kept immersed in water and free from light and air, and these conditions are fairly satisfactorily fulfilled in the inside of a stern tube, so that the very conditions that were previously destructive to the tail shafts themselves are now those that are relied upon in this apparatus to keep the covering material in good condition.

# LETTERS TO THE EDITOR.

*(We do not hold ourselves responsible for the opinions of our correspondents.)*

### GOVERNING ELECTRIC LIGHT ENGINES.

Sir,—To understand something which is new, not only by a mechanical detail, but also by its manner of action, it is necessary to have clearly in mind in what manner the usual electric regulations act. In Fig. 1, D is the dynamo, A B and C D are the mains. Connections from one main to the other by means of incandescent lamps, *a b c d*, or any other apparatus R are shunts, and the current in each of these connections is a shunt current, while the current from C through D to A is the main current. Now, if we wish that each lamp—for instance, *c*—should glow with the same brilliancy irrespective of the number of other lamps switched on, then we ought to have a constant voltage between the mains A B and C D. That, of course, implies that the mains are sufficiently large, so that the loss of voltage from A to B or C to D may be neglected. In a distribution at constant voltage, as is generally the case with glow-lamps, we must therefore distinguish the main current, or the current in the dynamo, which is essentially variable according to the number of lamps switched on from a shunt current which is or at least ought to be constant. Now in similitude to what is done with other regulators—for temperature, for speed, &c.—the electric regulator, such as Richardson's, for instance, is inserted there where the current ought to remain constant, thus in this case as a shunt, at R, Fig. 1, for instance. The regulator will now tend to maintain a constant current in R, and thus a constant voltage betwen A B and C D.

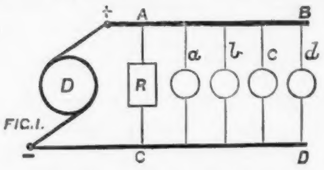

FIG. 1.

If the electric regulator R is inserted in the main current, Fig. 2, then it will evidently act so as to maintain a constant main current.

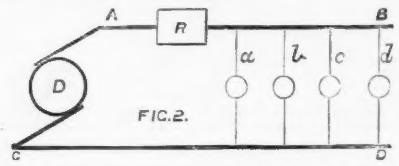

FIG. 2.

Suppose we have exactly the current which is wanted when only one lamp *a* is switched on. Now, if a second similar lamp *c* be added, then, as by the action of the regulator R, we have then again the same main current, we will have in each lamp only half that current. With three lamps each lamp will have only one-third the current we had originally in *a*. This arrangement of the regulator would be therefore entirely unsuitable for our purpose.

However, when we have arc lamps in series, Fig. 3, then we must insert the regulator R in the main current. This arrangement allows some lamps *c* and *d*, for instance, to be taken out of the circuit and then—of course when the circuit is closed again—the remaining lamps, *a c e*, will burn as before.

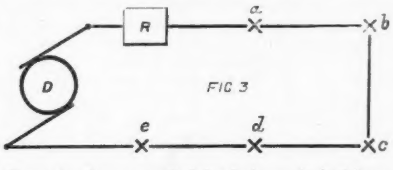

FIG. 3

The principle of the action of the electric regulator now in use—and which is, as said, the same as in regulators for temperature, speed, &c.—seems so natural and the only one possible, that the manner how the regulator must be connected to the circuit is often not, or not clearly, indicated. So, for instance, in the letter of Mr. F. Kadveitsch, on page 446 of your issue of November 23rd. We read there:—"The resistance of the main current (*sic*) is increased; consequently the voltage rises. The solenoid, being intercalated in the current, draws the iron core downwards." Though not decidedly said, it is obvious that the solenoid must be intercalated as a shunt, for when the voltage rises then the shunt current will increase, and thus draw the iron core downwards against the force of the spring, while the main current decreases when lamps are switched off.

We may therefore take it as settled that for a distribution at constant voltage the electric regulator must be inserted in a shunt, as in Fig. 1.

I may further state that any electric regulator should have, or at least should as nearly as possible approach to the following general properties: The movable part—and here I mean that part which is to be connected to the throttle valve or the expansion gear of the engine—should be at rest or in equilibrium for only one given strength of the current in the regulator. For if it could be in equilibrium for any other current, then it would evidently not move, and therefore not act to restore the original current strength, it would not regulate. Further, if there occurs an irregularity, then the movable part must move in a given direction, or in the reverse direction, according to the irregularity being above or below normal, and it should continue to move until the original current is restored, and then come at rest in its new position.

If we consider now my governing method, then we may state at once that in the case of a distribution at constant voltage, not any apparatus is to be inserted in a shunt current. Thus we see that Fig. 1, which I showed to be the only possible arrangement for a usual electric regulator in a distribution at constant voltage—for sake of simplicity we will only consider that case in the following explanation—is not applicable to my method:—Let we suppose a definite case. An engine driving a dynamo for a maximum of 50 ampères at 100 volts, and assume that each ten lamps of 0·5 ampères, each at 100, volts will correspond exactly with one actual horse-power.

Now, suppose ten lamps switched on, then the output of the dynamo is 5 × 100 = 500 watts, if we have the right voltage. According to our supposition we want exactly 1-horse power to give the required output, and if the the engine gives less, then of course the output of the dynamo must be less, and the ten lamps switched on will not receive the necessary voltage, say, only 90 volts. If the engine developes more than 1-horse power, then the output of the dynamo must be more too, and the lamps will get too high voltage, say, 110 volts. Now, to obtain 1-horse power we want to set the throttle valve—or expansion gear—T, Fig. 4, in position 1. If ten lamps more are switched on, then we want 2-horse power, and the throttle valve must be set in position 2. For thirty lamps 3-horse power are wanted, and the throttle valve must be set in position 3, or, in other words, when the throttle valve is set in such a position that the engine will develope 3-horse power, and if thirty lamps are switched on, then they will get the exact voltage, for as the dynamo receives from the engine 3-horse power, corresponding to an output of 3 × 500 = 1500 watts, and as each lamp takes 0·5 ampères, the voltage must necessarily be 100 volts.

But how will we know in the engine-house that 10, 20, 30, &c., lamps are switched on, and thus that the throttle valve must be set in positions 1, 2, 3, &c.? Or rather better, how will we obtain that the throttle valve is automatically set in the respective positions? Simply by inserting a suitable apparatus *v* in the main current, having a movable part which takes exact definite different positions, according to the different current strength corresponding with 10, 20, 30, &c., lamps in the circuit. I will discuss this apparatus further on, but to fix our mind, we may suppose it to be a wire coil or solenoid with iron core, the attraction being balanced in a suitable manner, by a spring for instance. Now, if this apparatus is so proportioned that the different positions of its movable part exactly correspond with the positions 1, 2, 3, &c., of the throttle valve, and if we connect that movable part to the throttle valve, then as soon as 10, 20, 30, &c., lamps are switched on, we will get immediately the required position of the throttle valve, and thus we will obtain for each number of lamps switched on the necessary horse-power, and therefore the required output and voltage from the dynamo.

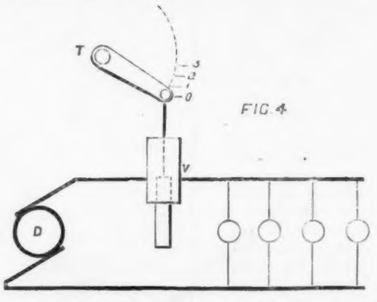

FIG. 4

You see that the electric connections for my governing method are similar to those indicated in Fig. 2. I showed that that arrangement is totally unfit for our purpose—constant voltage distribution—when a common regulator is used. It would therefore be nonsense to say that my method consists only in a change in the position of the regulator, for the apparatus V—Fig. 4—is not at all a regulator in the usual sense of the word. I showed before that the movable part of a regulator should only be at rest for a single current strength, and that if there occur an alteration, it ought to move in a given direction till the orginal current is restored, and then come again at rest in its new position. The movable part of the apparatus V, however, should only be at rest—or in a stable equilibrium—in a single position for a given current, and that position should vary in accordance with the current. The apparatus V could perhaps be named a "variator." I think it will be agreed that this state of stable equilibrium is much easier to obtain than the astatic movement in the common regulators, but perhaps it will be thought an insurmountable difficulty to obtain for each current exactly that position of the movable part required by the throttle valve. To this I may answer:—

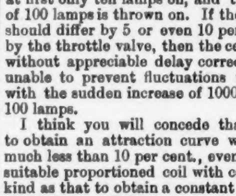

FIG. 5

(1) In the experiments in my laboratory, at the Polytechnical School in Berlin, at the laboratory of Professor Hospitalier, and at the Conservatoire des Arts et Métiers in Paris—reported by *l'Electrician* and *La Lumière Electrique*—I used the same coil, and had only to take a different iron core in some cases.

(2) There are a great number of electro-magnetic attraction apparatus from which we may take that which gives the most suitable curve. Moreover, we may also alter the movement of the throttle valve or expansion gear to suit the attraction of the variator, or a suitable mechanical device, such as a properly-curved excentric, may be used to transmit the movement of the variator.

(3) It is generally not at all necessary that the curve of the movement of the variator V corresponds exactly to that required by the throttle valve, as a relative large difference will only have a very small influence on the regularity of the engine. To explain this I beg it must be remembered that my governing method must be used in conjunction with a centrifugal regulator. Now suppose at first only ten lamps on, and that then suddenly the whole load of 100 lamps is thrown on. If then the new position of the variator should differ by 5 or even 10 per cent. from the position required by the throttle valve, then the centrifugal regulator will easily and without appreciable delay correct that, though it would be totally unable to prevent fluctuations in the light when it had to deal with the sudden increase of 1000 per cent. in the load, from ten to 100 lamps.

I think you will concede that it will not be a difficult matter to obtain an attraction curve with an approximation to within much less than 10 per cent., even without more complication than a suitable proportioned coil with core. The problem is of the same kind as that to obtain a constant voltage by the compound winding of a dynamo. Indeed, my method is for steam engine governing what the compound-winding is for dynamo governing, and just as a compound-wound dynamo will give a practically constant voltage, I maintain that only my method will practically prevent variation in the speed of the engine, while that is impossible with common electric regulators such as Richardson's, Willans', &c.

The Hague, December 1st. C. L. R. E. Menges.

### THEORY OF THE STEAM ENGINE.

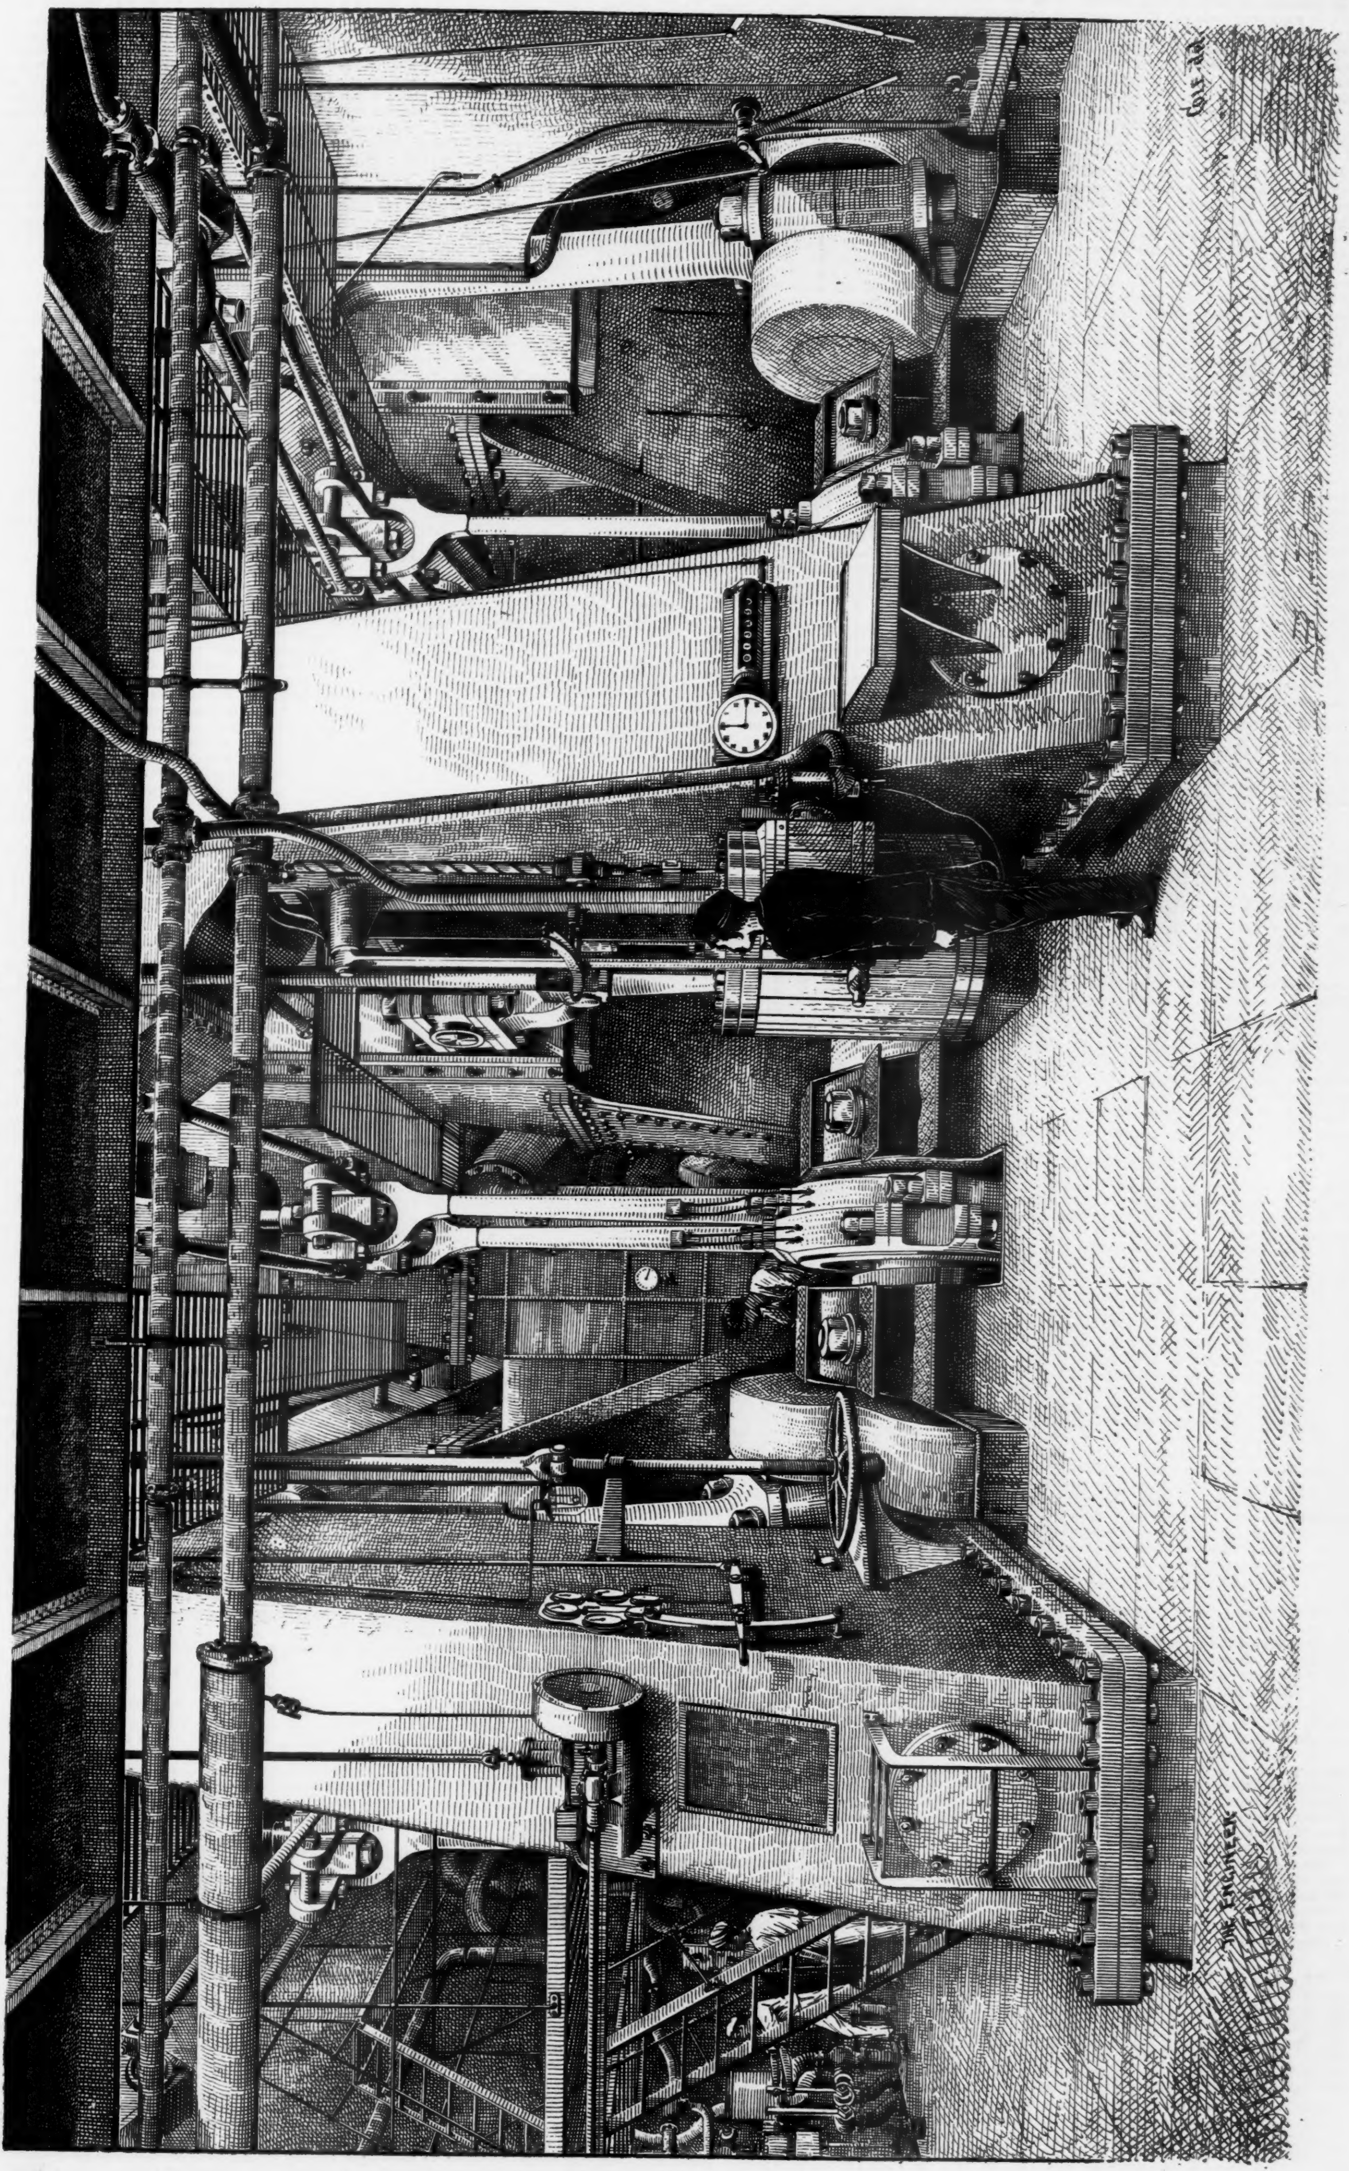
Sir,—In a former letter I gave Mr. Cross "three nuts to crack." Failing to "crack" any one of the three, he now writes a letter which he can hardly suppose I should consider a subject for serious reply. However, for the reasons mentioned in my letter appearing in your issue of the 30th ult., I will run it through as briefly as possible line by line.

(1) Will Mr. Cross refer me to any of my letters in which I have stated that "since the three angles of a triangle are equal to two right angles, therefore no heat engine can have a higher efficiency than that denoted by the fraction $\frac{T - t}{T}$?"

(2) He affirms that "the assertion that what is known as Carnot's theorem can prove of the smallest utility to inventors or designers of hot-air, steam, or gas engines is flatly untrue. Mr. Cherry ought to know perfectly well that it is untrue." Now this latter sentence appears to me presumptuous in the extreme. As a matter of fact, I have found the theorem of the greatest utility. Plausibly inventors frequently put forward preposterous claims to economy, which can be at once detected by a judicious application of the theorem. Hence, I have been able in several cases to prevent hesitating inventors by whom I have been consulted sacrificing their cash. You will doubtless remember a case in point, some years ago, in which an experimental engine was run on a "faked" brake.

(3) I am not aware that Mr. Cross has shown logically that "the fraction of the heat utilised in the cylinders of a good steam engine may be double that which, according to Carnot's theorem, it ought to be."

(4) He says, "I will go further, and challenge Mr. Cherry to prove." In point of fact, to prove that which I have distinctly asserted in my last letter is not proven. A very safe challenge surely, but, *cui bono*, if not to throw dust in the eyes of some of your readers.



COLE SC.
THE ENGINEER

IN THE ENGINE ROOM OF THE STEAMSHIP CALEDONIA—ON THE LOWER PLATFORM

*(For description see page 523)*

(5) He presents us with a long excerpt from the late Clerk Maxwell of respected memory, and appears to consider that an appeal to general experience is an inadequate form of proof. I think few physicists possessing the logical faculty will agree with Mr. Cross here. In the main, proofs of physical fact can be readily shown to depend ultimately on experience. In the present case, we have no experience on record of heat being conveyed from a colder to a hotter body without the expenditure of mechanical work. Does Mr. Cross consider that the universality of the law of gravitation throughout the visible universe rests on inadequate proof?

(6) As regards the three statements which he asks me to make. The first would occupy too much of your space and my time for categorical reply. The second would be answered in satisfying the first; and with reference to the third, I traverse the assertion made *in toto*. He then asserts that "no doubt his reply"—that is my reply—"will be that Carnot's theorem refers to a mathematical abstraction." This assertion again appears to me to savour of extreme presumption. My reply is nothing of the sort. I hope if Mr. Cross fails to appreciate my winnowing of his letter, the seed may not altogether fall on barren ground. He may note that Professor Smith even does not profess to defend him.

In the sentence of my letter appearing in your issue of the 30th ult., commencing, "Now, what Carnot's," &c., third line, "cannot" should be "can," and fifth line, "over the piston" should be "on the piston." Also, rightly or wrongly, I spelt such words as "cognize," "realize," &c., with a "z" and not an "s." HENRY CHERRY.

21, Festing-road, Putney, S.W.,
December 7th.

SIR,—It was Mr. Cross's letter of October 5th which gave rise to my letter of October 12th. It filled me with amazement to see that any one dreamed of obtaining greater efficiency than that indicated by $\frac{T - t}{T}$, where T and $t$ are the highest and lowest temperatures of the steam. This led me to think, and I still think, that such vagaries are greatly due to the slovenly teaching of thermodynamics in its application to the steam engine by writers on this subject.

Mr. Cross's letter in your latest issue, with his challenge to Mr. Cherry to find a flaw in his proof of October 5th, that the efficiency of a steam engine may be nearly twice as great as the theoretical efficiency, raised my curiosity to such a pitch that I took the trouble to examine Mr. Cross's proof carefully to see where the flaw is. The mistake is that he uses for the average pressure $\frac{150\,(1 + \log_e 10)}{10}$ —misprinted $\frac{150\,(1 + \log_e 2\cdot3}{10}$, which is the average pressure, on the supposition that the expansion is *isothermal*, and therefore that the steam is receiving heat from the cylinder while it is expanding, and this, of course, ought to be taken account of in estimating the efficiency.

Moreover, Mr. Cross uses 305·5 deg. Fah. for the temperature of dry saturated steam under a pressure of 150 lb. per square inch. Now, every book I have gives 358·5 deg. Fah as the temperature. On using this in the theoretic efficiency formula $\frac{T - t}{T}$, I get 17·7.

If Mr. Cross will calculate his mean pressure from $\frac{150\,(4\cdot29 - 3\cdot29 \times 10^{-\cdot304})}{10}$, which is calculated on the supposition of the expansion being adiabatic, he will get ·18, or 18 per cent. as his efficiency. As the work destroyed by the back pressure is omitted from the calculation, this is a little greater than the theoretical efficiency, 17·7 per cent.—see "Rankine's Steam Engine" §§ 297 and 298, and my treatise, pages 118-120. I am very much pleased with Mr. Cross's criticism of Maxwell's proof of Carnot's Principle —which is really Lord Kelvin's proof. I think Clausius' proof less objectionable. PETER ALEXANDER.

26, Smith-street, Hillhead, Glasgow,
December 10th.

### LOCOMOTIVES AND TRAINS.

SIR,—I am pleased to see that this matter has been so well taken up by your correspondents. I am strongly of opinion that our engines are being made too heavy in comparison to their boiler capacity. I cannot see the benefit of putting 19in. by 26in. cylinders in engines with only a little over 1000 square feet of heating surface, or even with 1200 or 1300 square feet.

The famous American engine, "999" has upwards of 1900 square feet, and still has cylinders only 19in. by 26in. There is a big contrast between the two. I am inclined to think that none of our engines would stand much chance of knocking her out, either as regards speed or hauling power. Although I do not believe in the 102 miles an hour speed, I should like to see her working over here, and I think the L. and N.W. corridor train would be a fair test; but there is little doubt but what she would be able to work it herself over any portion of the road.

I greatly dislike double engine running, but most of our railway companies make a practice of this of late. The L. and N. W. corridor is brought from London to Crewe and back by 1304 Jeannie Deans, and taken on to Carlisle by two of the Precedent class generally. Perhaps it may be necessary, but I think this might be avoided if one of the Greater Britain class was converted into a simple coupled engine with cylinders 20in. by 26in., as the position of the driving wheels is admirably adapted for the use of short coupling rods, and her boiler could be made to contain 2000ft. of heating surface. The L. and N. W. dining cars are very heavy, the kitchen cars weighing 33½ tons, from the particulars I have before me.

The other night two of the new Caledonian engines brought one of the mails into Carlisle, which consisted of a load equal to eighteen six-wheeled coaches. One of the big compounds was attached, Richard Trevithick, and she had the assistance of a coupled engine up the bank, when this was detached, and the compound brought it on to Crewe.

I should like to see one of the big compounds converted into a simple engine with 7ft. 6in. coupled wheels, 35 tons for adhesion, cylinders 20in. by 26in., and with a leading bogie.

Our express engines have greatly increased in weight. For instance, the L. and N. W. compounds 52 tons 2 cwt., North-Eastern engines 51 tons, and the Great Western of a similar weight; whereas the L. and N. W. old coupled engines weigh only 33 tons, and have 1102ft. of heating surface; and I think, therefore, the heating surface of these heavy engines should be correspondingly increased.

The one drawback of the compounds is the starting, as they are only equal to a single engine with cylinders 15in. by 24in. until the large cylinder gets into working order.

In conclusion, I think engines could be built which would haul any of our express trains without the assistance of a second engine.

December 8th. J. G.

SIR,—Does Mr. Bowles refer to the North-Eastern 1496 class of engine? This engine was constructed in 1884 by Messrs. R. and W. Hawthorn, Newcastle-on-Tyne, to the designs of Mr. Alexander McDonnell, then locomotive superintendent. The following are a few leading dimensions of this class of engine:—Cylinders, 17in. by 24in.; driving wheels, 6ft. 8¼in. diameter; trailing wheels, ditto; boiler pressure, 140 lb. per square inch; total heating surface, 1030·25 square feet; grate area, 16·8 square feet. Weight in working order: On the bogie, 12 tons 4 cwt.; on the driving wheels, 15 tons; on the trailing wheels, 12 tons 6 cwt. Total, 39 tons 10 cwt. Weight of engine and tender in working order, 67 tons 10 cwt.

If this is the engine referred to by Mr. Bowles, I would point out that the favourite Tennant class, with 18in. by 24in. cylinders and 7ft. wheels is far superior both as regards power and speed; but to compare such an engine to Mr. Worsdell's 1622 class with their 19in. by 26in. cylinders, 7ft. 1in. driving wheels, heating surface 1341 square feet, and a boiler pressure of 180 lb. to the square inch, is too absurd to notice. W. J. BARKER.

Hyde Park, Leeds, December 10th.

SIR,—I agree entirely with Mr. Norman Macdonald in your last issue, p. 486. We have indeed had a storm in a teacup over the North-Eastern engines, but when that gentleman goes on to say that it was "the big engine helping the small one," he is as wrong as wrong can be. Engine No. 1622 was the big train engine, with 19in. cylinders. It was this big one that was short of steam, and could not work its brake. The small engine No. 905 was taken on at Darlington in front to help the big one to York. What does Mr. Macdonald refer to when he says there was "an injured brake pump?" The pump was right and the brake was right, but with a falling steam pressure there was not enough steam to work the pump and obtain the necessary air. Mr. R C. Dowie is quite right, the modern express engine does not lose time, the time goes at the stations. A PRACTICAL MAN.

December 10th.

SIR,—I have read with interest your correspondence *re* train speeds, and particularly "Permanent Way's" remarks on Caledonian engines. I beg to correct a slight error. The Caledonian Co. has now, to the best of my knowledge, no engines with 19in. cylinders. One was built with cylinders of that size and Bryce-Douglas valve gear, as stated in Mr. Bowen Cooke's book, but this gear was removed, and 18in. cylinders with ordinary excentrics substituted some years ago. The latest express engines No. 13 to 17 have 18in. cylinders. Among other companies that have 19in. cylinder express engines should be included the Highland—93 class —and if I am not mistaken, the Great North of Scotland latest express, built in 1893—80 class—have cylinders of that size. The Highland have also a class of six-coupled bogie engines—Nos. 103-117—with outside cylinders 20in. by 26in. These engines which, however, can hardly be counted as express, are claimed to be the largest in Great Britain. STRATHNAIRN.

Perth, November 30th.

SIR,—Full particulars of the North-Eastern Railway, MacDonnell, engine appeared in the *Railway Engineer* for April, 1884. The weight is there given as 37 tons 10 cwt. I do not recollect having heard of the "pick-up" being used on the tenders of these engines, but these are unquestionably the MacDonnell engines referred to by your correspondents. J. E. D.

London, December 10th.

SIR,—In reply to "E. R.," I was of course referring to the South-Eastern Railway. W. B. THOMPSON.

London, December 11th.

### TRACTION ENGINES.

SIR,—I have for many years had a good deal to do with traction engines for road hauling. I have been a collector for years of information referring to traction engines and their wheels. I have before me two scrap books, containing newspaper cuttings referring exclusively to traction engines. I find in the great majority of cases the diagonal cross-bar wheels have been the main cause of getting the traction engine into trouble and disgrace. Any practical man knows that the common cross-bar wheels slip or skid. Could anybody devise a better arrangement for tearing our roads in pieces than this barbarous cross-bar wheel, no matter what the road is made of, when a cross-bar wheel slips—which it is constantly doing?

More or less it tears the road in pieces. It is quite useless writing on this subject, unless we adhere strictly to facts. Is it or is it not a fact, that there is amongst many of the traction engine builders a certain amount of combination, both as to prices and as to what shall or shall not be introduced in the shape of improvements? Now, what is really wanted for traction engines is a wheel with considerable bearing surface on the road: a wheel that will not slip or damage the road—in fact, a wheel as near to the one suggested in one of your articles, viz., india-rubber tires, which we all know are far too expensive and difficult to keep in repair. One of your correspondents suggests a wheel with a smooth surface 18in. wide. We know very well a wheel of that width, with a rigid periphery, on the majority of our roads, particularly a paved road, would seldom have more than a fraction of a square inch of bearing surface on the road at once, and this fraction is all the adhesion the engine has to enable it to draw its load. If an engine could depend upon adhesion, we know it would use very much less water, less fire, less wear and tear, and the men would be enabled to know when they were likely to finish their day's work.

I am very much inclined to think, if our surveyors who have had experience of cross-bar wheels were to give us their opinion, a great majority of them would say, Give us a better wheel.

We know great complaints are made about damaging the roads by slipping, and the great vibration caused in passing through towns to the adjoining property by the cross-bar wheels. They act like spur or cog wheels. We are mostly agreed that we want an improved traction engine, and my opinion is that we might make a beginning by asking the traction engine makers to give us a better wheel.

Then, again, in reply to "J. H. M.," in last week's ENGINEER, I quite agree that all engines should be licensed, but at the same time only two classes of licences should be issued, one for agricultural and one for hauling engines. Weight of engine should not be taken into account, as it is well known that engines, as at present designed cannot be weighed correctly to correspond with the weight plates placed on them by the makers.

With regard to the driving wheels, it is high time the cross-bar wheel was abandoned for hauling engines, as being inefficient and destructive, it being, as Mr. McLaren says in his paper read before the Civil Engineers, a barbarous arrangement. In the same paper he denounces single crank compound engines as now recommended by your correspondent, "J. H. M., of Leeds."

Wood block wheels are working daily on macadamised roads, and have been for years, without complaint from surveyors. Then why say they are too heavy? I wish that their actual performance was more fully inquired into, then I think any prejudice against them would cease, and they would gain more friends amongst makers and users, who do not know how well they are acting. E. R.

Manchester, December 11th.

### INDUCED *v.* FORCED DRAUGHT.

SIR,—It was my intention to have made a few remarks in the discussion that took place last week on the paper read by the engineer-in-chief at the Institution of Civil Engineers, but owing to want of time the chairman was unable to call upon me. In the paper reference was made to experiments with induced draught on board H.M.S. Gossamer; but as no details were given, perhaps I may be allowed to supplement the few remarks of the engineer-in-chief. The Gossamer has two stokeholds, each containing two boilers. The uptake of the forward boilers was fitted with my system of induced draught, the two after-boilers retaining the forced-draught system; everything in both boiler-rooms remaining the same, the object, it appears, being to test the merits of the two systems on equal conditions. The tubes of the boilers were 1½in. internal diameter, with reduced ends in the fire-box as a preventive against leaky tubes. The boilers, notwithstanding all this, had suffered considerably from leaky tubes, which had been rolled and re-rolled to make them tight. As a further precaution ferrules were added, so that the 1½in. tubes were reduced to ⅞in., or to nearly one-third of the actual tube area. These conditions may serve to explain to some extent Mr. Durstan's inference that "as regards absence of leaky tube ends no superiority can be claimed for induced draught," as in this case old sores broke out on several occasions to interrupt the trials, but after the tubes were again made tight nothing of the sort occurred. It is a system of induced draught which is used on every locomotive, and if that caused boiler tubes to leak it could certainly not be so universally adopted with immunity. At high speeds the exhaust will produce a partial vacuum in the furnace equal to 10in. or 12in. of water, more than sufficient to draw off five times the amount of heat generated in the furnace, so that concentration of heat is impossible.

Reverting to the "Gossamer" trials, I may be allowed to mention that the final trial between induced draught and forced draught was a run of twenty-four hours at 1000-horse power. This was completely carried through by the former, the horse-power being exceeded, whilst it was found impossible to carry it out at all with forced draught, and the trial had to be abandoned.

Pocock-street, Blackfriars, London, W. A. MARTIN.
December 12th.

### LABOUR AND LUXURIES.

SIR,—In despair of finding any probable basis for "Y. X.'s" views as to gold in more familiar treatises, I turned up the half-forgotten "Political Economy," of Malthus, the very writer whose supposed neglect of ethics caused impulsive moralists to dub political economy "the dismal science"; and in the very opening of his treatise I find that very chapter of the "Wealth of Nations," to which I at first called "Y. X.'s" attention, cited as the keystone of Adam Smith's work; and, further, he quotes, with critical approbation, the conclusion of the following passage, which, to my misfortune, I overlooked in my previous reference: "Whatever, therefore, we may imagine the real wealth and revenue of a country to consist in, whether in the value of the annual produce of its land and labour, as plain reason seems to dictate, or in the quantity of the precious metals which circulate within it, as vulgar prejudices suppose; in either view of the matter every prodigal appears to be a public enemy, and every frugal man a public benefactor."—"Wealth of Nations," Book II., Chapter III., pp. 343, Thorold Rogers' Edition.

In a subsequent passage of the chapter Smith explains at length that he is referring, not to the ethical but to the economical side of man. So that the word on which "Y. X." poured his contempt actually occurs in the central passage of the keystone chapter of the founder of our science. See also on the previous page:—"The same quantity of money cannot long remain in any country in which the value of the annual produce diminishes. The sole use of money is to circulate consumable goods." Be it clearly understood that by money he means gold and silver, the precious metals. And how can "Y. X." reconcile this:—"The quantity of money which can be annually employed in any country must be determined by the value of the consumable goods annually circulated within it," with the "instructive" (?) story of the man who found gold in a rivulet, which "Y. X." offered to us as an answer to one of the most complicated questions that can be asked, an outline of the answer to which takes some three chapters of Mill.

"Y. X." began by attacking what he was pleased to term a popular fallacy, and referred us to the most famous economists; but he has already admitted that his views on gold are contrary to that of *some* eminent economists: if he had said *all* his statement would have been accurate. The study of gold as such is a branch of physics. It is a part of wealth; that is—as the first chapter of any treatise will show, in relation to the wants and desires of men—that gold concerns political economy. What he says about the time element is the exact contrary to what all economists allege, and the story of the broken window which he assigns to ethics has been a favourite ever since it was so charmingly told by Bastiat, who, I need scarcely say, assigns to the ignorant crowd the view taken by "Y. X.," and that of "J. C. S." to the enlightened economist. There is a translation in Mrs. Fawcett's "Political Economy for Beginners." I hope that before "Y. X." again rushes into print with absurd charges of confused thought on the part of others, he will acquaint himself at all events with the ordinary definitions and postulates of the science he misrepresents. W. A. S. B.

SIR,—As has been conclusively proved by Flürscheim and Hertzka, no injury is done in the long run to the poor by expenditure on luxuries; indeed, if the entire surplus savings of the rich were so spent, lack of employment would soon cease and wages rapidly rise. The true cause, the only cause, of so-called "over-production," and the consequent idleness of multitudes of willing workers, is that the accumulations of the rich are not expended in the purchase of goods, whether necessaries, luxuries, or genuine capital—*i.e.*, machinery, buildings, ships, &c.—the creation of which must give employment to labour, but devoted in large measure to the further acquisition of titles to land, bonds, and other tribute rights. This, so far from increasing the demand for labour, only lays burdens upon industry and restricts the opportunities for employment, thus again lessening the demand for commodities. Hence the ever-recurring phenomena of what is in reality "under-consumption," trade depressions, and commercial crises. EVACUSTES A. PHIPSON.

Selly Oak, December 10th.

SIR,—If your correspondents "W. A. S. B." and others, instead of arguing with "Y. X." and attributing to him statements which, so far as I can see, he has not made, would state the case from their point of view, something would be gained.

May I ask "W. A. S. B.," then, to show how gold may be used in such a way that it can do most good—I mean commercially, not ethically? There is at this moment in the country an enormous amount of money. It would be interesting to learn how it can be best used. Not, I should think, in producing more commodities, of which at present we have more than we can either consume or sell. M.

Cannon-street, December 10th.

### SIMPLEX GAS ENGINES AND THE PANTIN FLOUR MILLS.

SIR,—The letter from "Progress"—which you published in your number of the 7th inst.—is indicative of the change now taking place in the production of motive power, and is one that I think most engineers will endorse, coupled with the fact of there being already so many makers of gas engines and so sharp a race for pre-eminence in this branch of the engineering business, proves that there is coming a general belief in gas—at any rate for small powers. The attempts made in this country hitherto for larger powers do not appear to have been so successful as in the smaller ones. The Otto principle for small engines seems to answer admirably and commercially, it being of a cheap form to make; but for higher powers I agree with "Progress," that something better is required, and I may I hope be allowed—without appearing egotistical—to refer him to my patents of 1893, Nos. 6453 and 9216. As to gas producers for bituminous coal: in this there appears to be considerable difficulties, but these will no doubt in time be overcome. J. C. R. OKES.

London, December 11th.

### THE FLYING MACHINE.

SIR,—Referring to the letter of "Contest" in last issue, may I suggest that a pendulous gravity-governor—which need not be too heavy, but should have plenty of leverage—might regulate the angle of the "tail" or the developed propulsive action of vertical screws on my system fitted at the ends of the air-ship to keep an even keel and lift also when desired.

It is obvious that the action of such screws could also lift, lower, keep steady, propel, reverse, alter speed, and nullify it; and suit the varying conditions of the fluid—in air as in water.

Selthurst, S.E., December 8th. ROBERT MCGLASSON.

## IN THE ENGINE ROOM OF A P. AND O. STEAMER.

It is practically impossible to convey an accurate impression of the appearance of the engine room of a great modern steamer by photographs. There is not sufficient light available, and what there is is uncertain and unsuitable for the photographer's purposes. Again, it is seldom possible to secure a sufficient distance between the camera and the portion of the machinery to be photographed. Nothing remains then but for an artist to make sketches, and to do this makes no small demand on the artist's skill and experience. We venture to think that our reproductions of drawings made in the engine room of the Peninsula and Oriental Co.'s new and splendid steamship Caledonia will convince our readers that, difficult as the task is, it is not impossible.

These drawings are seven in number. The first, on page 521, shows the lower platform, as seen from the port side of the ship, with Messrs. Brown Bros.' reversing gear. The Caledonia is a single-screw ship. Looking through the space between the A frames, the condenser is seen. On the extreme left is the bulkhead between the engine and boiler rooms. Against the bulkhead stands a Weir's feed pump. The small "wheel" on the A frame is the cylindrical casing of a Durham and Churchill marine governor. Immediately under it is the engine-room log slate. The clock, counter, and desk on the other frame speak for themselves. The grating at the top is the second platform at the level of the links.

The second view, on page 525, explains itself. We have here a drawing which conveys an excellent idea of the great size of the crank shaft and connecting-rods. The crank guards are supposed to be unshipped, and we are looking astern through the A frame.

The third view, on page 528, is taken on the third platform. At each end we see one of the two high-pressure cylinders. To the right of the centre is the top of the valve casing for the intermediate cylinder, and at the other end can be seen the rocking lever by which the high-pressure valve spindle is driven. An enlarged view of this lever will be found on this page. The pipes seen in the background are the main steam pipes; those in the foreground are the exhaust pipes to the intermediate cylinder. The pipes are all very heavily clothed with non-conducting composition, which greatly adds to their apparent diameter. The composition is covered with canvas, and that again with wire netting secured by iron bands; these are painted black, the canvas and netting light stone colour. Under the grating, in the extreme left-hand corner, may be noticed one of the exhaust pipes from the low-pressure cylinder to the condenser. Higher up in the picture, but still to the extreme left, is seen the steering engine. The inverted dome at the top is a portion of the Weir feed-water heater.

The fourth view page 527 was taken on the top platform, looking astern. In front is seen the piston valve casing of one of the high-pressure cylinders, the high-pressure cylinder, and the lifting gear for the intermediate cylinder cover attached to the transverse girder, in which position it remains while the ship is at sea. In the left-hand front corner is the upper portion of the Weir heater. The main steam stop valve can be seen at the off-side of the high-pressure valve casing.

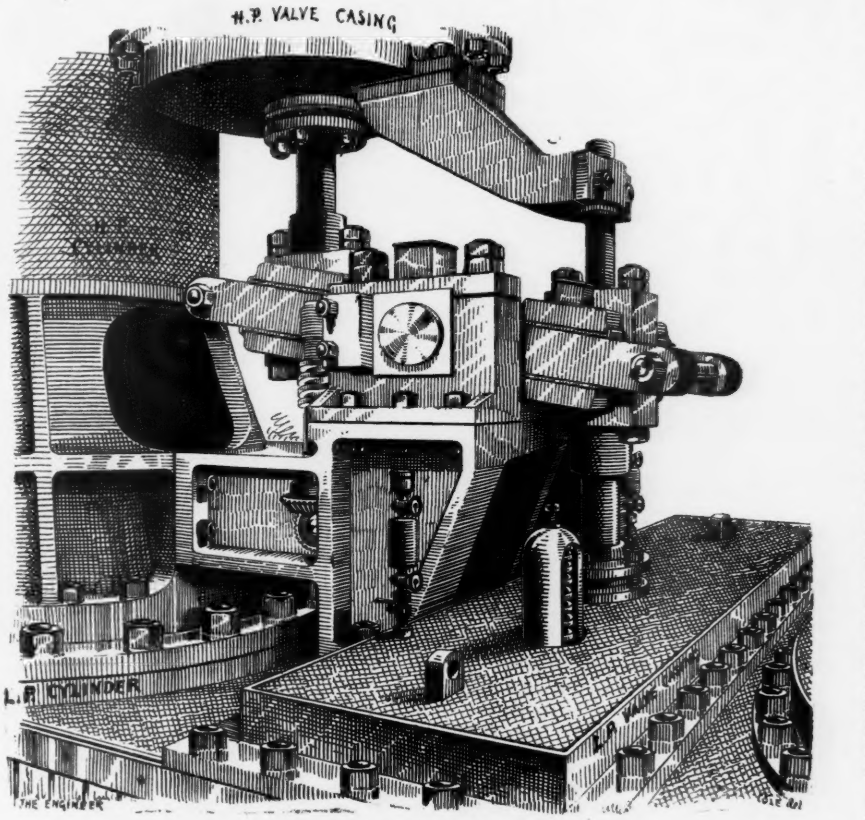
The fifth view page 531 affords an excellent example of the difficulties to which we have referred as standing in the way of an artist. Here it has been found necessary to suppose the main engines to be removed altogether, in order that the electric light engines and dynamos may be seen without obstruction. At the extreme left is seen the spare crank shaft up-ended against the bulkhead. Close to it is the hydraulic engine, supplying water under pressure for working derricks, &c. Right in front is a donkey pump.

The electric lighting on board this ship has been carried out by Messrs. Siemens Bros. and Co. There are 734 incandescent lamps of 16-candle power fitted up in the vessel, besides eight deck lanterns with three lamps each for use when discharging cargo, and two arc lamps for use in passing through the Suez Canal, one of 50 ampères in a projector for use at the bows, and the other of 20 ampères for a mast-head light. These lamps if all running at once would require 52 kilowatts, and this is provided for by three sets of generating plant, each of 23 kilowatts; usually one set is held in reserve. The three sets are quite similar, and each consist of a Siemens H.B. $\frac{15}{20}$ dynamo for 220 ampères at 105 volts, coupled direct to a Tangye Archer-type vertical compound engine, with 8in. and 16in. cylinders and 10in. stroke, running at 220 revolutions per minute, and working with 150 lb. steam pressure. We illustrate an engine and dynamo on page 533. Both slide valves are Trick ported. The wiring is carried out with highly-insulated india-rubber covered wires in teak casings, except in the engine and boiler-rooms, where they are enclosed in iron pipes; the iron structure of the ship is used for the return circuit. Joints in the wires are avoided by the use of special junction boxes, each serving for ten lights. The Caledonia is the forty-fourth Peninsular and Oriental vessel fitted by the same contractors, who besides have eight others just completed or in hand.

The sixth view page 527 on the starboard side of the engine room illustrates the two circulating pumps set at an angle. A portion of the condenser has been broken away in order that the Kingston valve may be seen. Just ahead of the forward centrifugal is a duplex pump. At the top left-hand corner is a portion of the Weir heater.

In our impression for September 14th we illustrated and described the Caledonia. She is a ship of 7500 tons, and 11,000 indicated horse-power, constructed and engined by Messrs. Caird and Co., Greenock. She is 486ft. long, 54ft. beam, and 37ft. deep. She has accommodation for 320 saloon passengers and 150 second cabin passengers, but no steerage accommodation whatever, none being provided in the Peninsular and Oriental Company's steamships, simply because there is no demand for it. She has space for 1500 tons of cargo. She is commanded by Capt. Andrews, and Mr. J. Stevenson is chief engineer. Her crew numbers about 300 all told, largely composed of Lascars and Seedy boys. The ship sailed on her maiden voyage, it will be remembered, on the 5th of October. On her trial trip, run from the Clyde to Queenstown, her maximum speed was 18·2 knots, a highly satisfactory result. She has four masts and two funnels.

Her engines very closely resemble those of the Campania and Lucania—illustrations of which, as they stood in the shops of the Fairfield Company, will be found in our impression for October 13, 1893. That is to say, there are five cylinders driving three cranks. The engines farthest forward and farthest aft are tandem. The central crank is driven by a single cylinder, the intermediate. Thus the two high-pressure cylinders exhaust, as shown in our third view, into the valve chest of the intermediate cylinder, and that cylinder in turn exhausts into the two low-pressure cylinders immediately under the high-pressure cylinders. The Atlantic liners have twin screws, the cylinders for each screw being two high-pressure 37in., one intermediate 79in., and two low-pressure 98in. in diameter. These are intended to indicate about 15,000 indicated horse-power, or 30,000 for the two.



VALVE GEAR ROCKING LEVER

The Caledonia has, as we have said, only one screw. The cylinders are two high-pressure 33in. diameter, one intermediate, 69in., and two low-pressure, 84in. diameter; which corresponds to one high-pressure cylinder, 46¾in. diameter, one intermediate 69in. diameter, and one low-pressure, 118¾ inch. The latter size is too great, and a far better result is got by using five cylinders instead of three. The turning moments are more regular and the risk of a broken cylinder is reduced. The high-pressure piston valves are, as we have said, driven off the low-pressure valve spindles by rocking levers, as shown. The piston valves might have been placed directly over the low-pressure valves, but the ports would then have been much too long, and the unbalanced weight would have been very great, the low-pressure slide alone weighing nearly 1½ ton; as it is the piston valve partly balances the weight of the slide valve.

The annexed tabular statement gives the principal dimensions of the Caledonia's engines.

The propeller is of manganese bronze, and is four-bladed; the diameter over all is 21ft.; the blade surface is 129 square feet; the pitch is variable, between 28ft. 6in. and 31ft. 6in.; when she sailed on her first voyage it was set at 30ft. 6in.; the length of blade is 9ft. 7¾in.

Steam is supplied by three double and four single-ended boilers. They have all the same diameter—15ft. The total number of fires is thirty. The heating surface in the three double-ended boilers is 14,139 square feet, and the grate surface, 358·8 square feet; the surface in the four single-ended boilers is 9870 8 square feet, and the grate surface is 229 2 square feet; thus the total heating surface of all the boilers is 24,000 square feet, which allows nearly 2¼ square feet per horse for 11,000-horse power, and nearly 19-horse power to the square foot of fire-grate.

*Dimensions of the Caledonia's Engines.*

| | |
|---|---|
| Number of cylinders ... ... ... ... ... | 5 |
| Diameter ... ... ... ... ... ... ... ... | 33in., 69in., 84in. |
| Stroke ... ... ... ... ... ... ... ... | 6ft. |
| Diameter of piston-rods ... ... ... ... | 11½in. |
| Valves:— | |
| High-pressure .. ... ... ... ... ... | Piston |
| Intermediate ... ... ... ... ... ... | Piston |
| Low-pressure ... ... ... ... ... ... | Slide |
| Crosshead pins—diameter ... ... ... ... | 11½in. × 12in. |
| Crank cheeks ... ... ... ... ... ... ... | 17½in. thick. |
| Excentric rods ... ... ... ... ... ... ... | 7in. at centre × 13ft. |
| *Diameter of thrust shaft ... ... ... ... | 21⅛in. |
| Number of thrust blocks ... ... ... ... | 2 |
| Total number of collars ... ... ... ... | 26 |
| Total surface ... ... ... ... ... ... | 6190 sq. in. |
| Diameter over collars ... ... ... ... ... | 28½in. |
| Diameter inside collars... ... ... ... .. | 21in. |
| Length of tunnel bearings ... ... ... ... | 2ft. 6in. |
| Number of tunnel bearings... ... ... ... | 8 |
| Diameter of tunnel shaft couplers ... ... | 41in. |

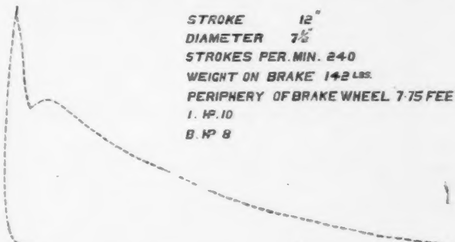
The ship is altogether a very splendid specimen of modern marine naval architecture. We have to express our thanks to the Peninsular and Oriental Company for the facilities afforded to our special artist while making his sketches.

## THE SMITHFIELD CLUB SHOW.

The show of machinery and implements in the Islington Agricultural Hall this week is not quite so large as in previous years, many of the occupied spaces in the implement and miscellaneous machinery departments not being filled, and numerous spaces being left quite vacant. There is apparently less reason for exhibiting on the part of the makers of some classes of machinery; while others, whose trade is either local or who have no novelties of importance, are unwilling to incur expense not warranted by the depressed condition of the farming industry in many parts of England. Most of the manufacturers of first-class engines and machinery have as much to do as they want, and several have done a larger foreign trade this year than ever. Almost all of the well-known firms exhibit at Islington, and have a considerable collection of their manufactures, and they thus provide a rendezvous for those who find the Smithfield Club Show a convenient place and time for business purposes. There are, however, few novelties in the Show to which we can draw attention.

One of the few novelties is the oil engine exhibited by Messrs. Howard, of Bedford. It is a well-finished 8 brake horse-power oil engine, the mechanical details of which are very simple. Like all others it works on what is known as the Otto cycle. It is of the type which is included in Classes 4 and 6 of our classification of these engines, namely, one which receives and converts the oil into a gaseous vapour in a vaporiser separately heated by an oil lamp with forced air combustion; and in which ignition is effected by an ignition tube, heated by an oil lamp with forced air combustion.

The oil is injected into a heated vaporiser, where it is met by a current of heated air and vaporised before it enters the cylinder, there to be mixed with the proper volume of air to form the combustible charge, which, when compressed by the return stroke of the piston, is fired by the ordinary ignition tube. A screw adjustment, varying the stroke given to the pump plunger, determines the quantity of oil for each explosion in the cylinder, the oil being admitted by an oil regulator, which is controlled by the hit-and-miss finger of the Holt governor. The arrangement and form of the vaporiser are shown by the



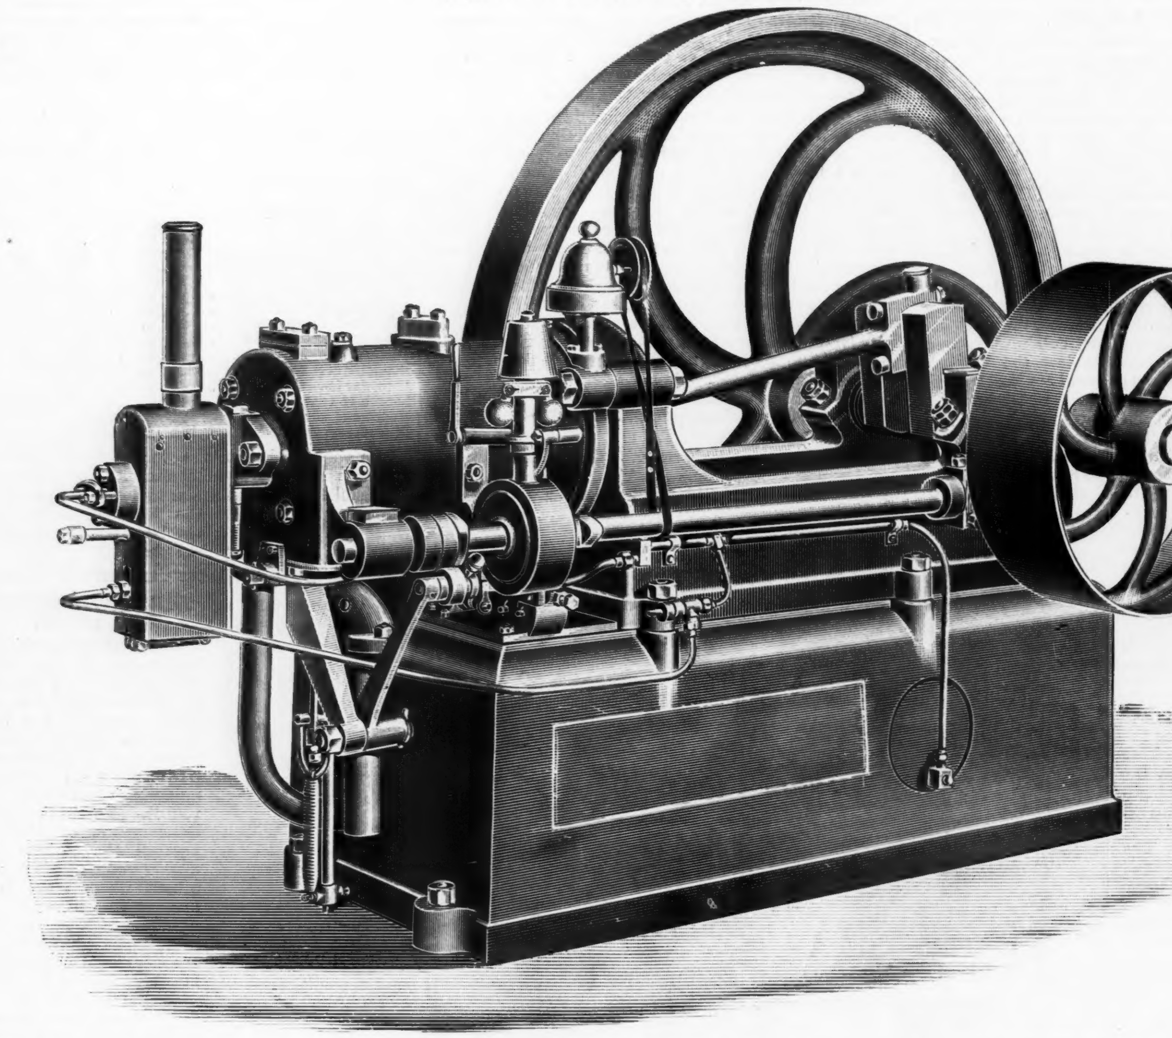
INDICATOR DIAGRAM—HOWARD'S OIL ENGINE

---

*Lucania's shaft 25¼in

# EIGHT-HORSE POWER OIL ENGINE

MESSRS. J. AND F. HOWARD, BEDFORD, ENGINEERS



engravings Figs. 1 and 2 herewith, the vaporiser being shown partly in section from a rough sketch. In this A is the back end of the cylinder, to which an inclined casting B is fixed. In the casting, section of which on the line N N is given in Fig. 2, there are two long round passages, and at the lower part is a flat passage G, this passage being the final gasifying chamber. Oil enters at D through a fine hole, through which it is injected under a small pressure into and hits the lower surface of the passage E. A small quantity of air is admitted by the valve V into the passage F, where it is heated. At the upper end of the passage F it enters the passage E, where it is further heated and comes into contact with the oil jet from the pipe D. By a connecting port at the lower end of the passage E, the air vapour passes into the hottest passage G, where the vapour is converted into a gas and passes into the working cylinder, when permitted to do so by the lifting of the valve W. The vaporiser is surrounded by an asbestos-lined case C, surmounted by a chimney H, and below the vaporiser is a lamp L, which heats the ignition tube T as well as the vaporiser. The bottom surface of the latter has cast upon it a number of pointed projections, which increase the heat receptivity of the bottom part of the chamber C. The passage G when it enters the valve case K is directed so that it passes over the valve, and the ignition tube T enters a separate port open to the cylinder.

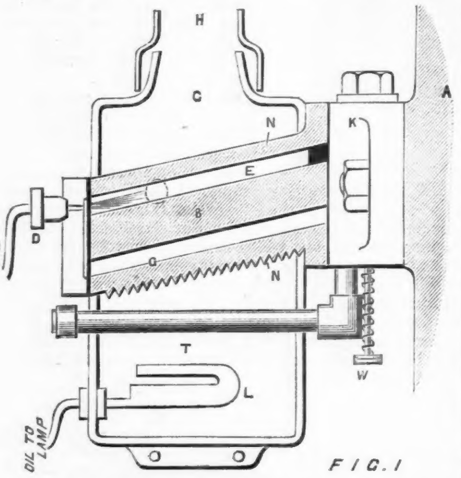


FIG. 1

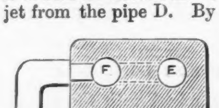
Fig. 1—VAPORISER, HOWARD OIL ENGINE



SECTION N.N FIG. 2

An indicator diagram from the engine is reproduced by the engraving on p. 523. It is typical of a number which have been shown us by the makers, and is from an engine with a 7·5in. cylinder, 12in. stroke, 240 revolutions per minute, and using no oil. The maximum pressure shown by the diagram is 255 lb., and the brake horse-power is given as 8, with 10 indicated horse-power.

Messrs. Hornsby and Sons exhibit two of their oil engines, one a portable engine similar to that shown at Cambridge, but the side frame has been made stronger, the height of the centre of the cylinder above them lowered, and stay rods between cylinder and brackets dispensed with. They have also made a valuable addition in the form of a simple and powerful clutch for driving the wheel from which the power of the engine is taken. It is a radial action clutch operated by toggles and a sliding collar and lever in an accessible position. The collar and lever are not subject to wear when the clutch is in gear. By using this clutch the load may be started after the engine is running, and the starting is thus made a comparatively simple job, and no time is lost taking off and putting on the belt.

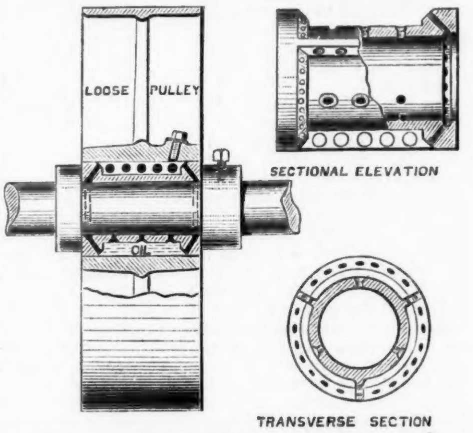
Messrs. Robey and Co. show an improvement in the starting lamp and fan of their engine, which reduces the time taken in heating the vaporiser and starting.

Messrs. Priestman Bros. exhibit two of their engines, one being a vertical launch engine fitted with their McGlasson reversible screw propeller, which enables the boat to be reversed in direction and manipulated without reversing the engine, or in any way interfering with its running. Messrs. Priestman have now a number of these screws at work with excellent results, and that exhibited at Islington shows how compact the screw gear is. Messrs. Priestman inform us that they have recently supplied an engine of this type of no less than 65 brake horse-power for use as auxiliary power on board a large sailing vessel, and have at present orders in hand for three more engines of the same size for trawlers on the East Coast fisheries. These engines are, however, we understand, double-acting, and two impulses are thus obtained, there being two cylinders, per revolution. The front end of the cylinder is closed, and a piston-rod employed, so that with the Otto cycle and no misses there may be one impulse in each cylinder per revolution.

Messrs. Robinson and Andrew, Wantage, exhibit amongst other things a neat little vertical engine of the turned front column type, and intended for small electric lighting plant; and they show a neat arrangement of stop valve on a vertical engine, which also serves as the regulating valve operated by the governor.

Messrs. Aveling and Porter exhibit a fine-looking road locomotive, with 7ft. 6in. wheels, and mounted on springs This we shall describe in a future issue.

Amongst the miscellaneous exhibits Messrs. Smith and Grace, of Thrapston, and 35, Queen Victoria-street, exhibit the new self-oiling loose pulley, illustrated by the accompanying engraving. It will be seen that the box of the pulley is made of large dimensions, and in it is fitted a large bush which is externally chambered, so that when in place in the pulley it provides a large annular oil space, only interrupted by perforated ribs. This space being filled with oil, perfectly and automatically lubricates the part of the shaft upon which the pulley runs, and only needs re-oiling at long intervals. A very great objection to loose pulleys is thus entirely removed. Experience proves it to work with complete success. A new mill for breaking down maize in large quantities is shown by Messrs. E. R. and F. Turner. The rollers used for the purpose are grooved, and are of chilled iron of the same character as that of the rolls used in the roller flour mills by the same maker.



SECTIONAL ELEVATION

TRANSVERSE SECTION

SMITH AND GRACE'S SELF-OILING LOOSE PULLEY

Messrs. John Crossley and Co. exhibit some chaff cutters with Mr. S. Edwards' new arrangement of the guide pieces for the rising roller, by which a clear way between the side cheeks is secured, the hay or straw meeting nothing in its passage to the knives, which is not rotating. The machine is also made with a wheel cover, and every part of the gearing is cased in. Several makers exhibit chaff sifting machines and machines for taking dust out of the chaff. There is no indication at this show of what the makers will enter for the Royal Agricultural Society's competitive trials next year for haymakers.

THE ENGINEER
COLE DEL

## RAILWAY MATTERS.

An order for four locomotives and tenders for a Portuguese railway has been placed with Messrs. Neilson and Co., of Glasgow.

At the beginning of this year the total length of the railroads in Austria was 9918 miles, with seventy-six different proprietors, among which were five different governments, adjacent States having short sections of lines on Austrian territory.

The lines of railway in Park-avenue, New York, owned by the New York Central, the Newhaven and the New York and Harlem Railway Companies, are being removed and elevated similarly to the well-known elevated system in that city. The structure which is to carry them will span the centre of the road, which is 140ft. wide, the elevation of the tracks restoring to it a central area nearly 60ft. wide.

The construction of the proposed Jungfrau Railway has been sanctioned by the Swiss authorities. As planned, the railway will ascend the upper part of the mountain by a series of spiral tunnels. The railway will end on a little rocky plateau on the western slope, and a vertical elevator will carry passengers up the final ascent. A look-out will be made on the narrow summit ridge by blasting.

Although the New South Wales Government has offered to increase his salary by £1000 per annum, Mr. Eddy, their Chief Commissioner for Railways, will not accept a renewal of his term of office, which expires in October next. Great praise is bestowed upon him by the Government and the Press in the Colony for his administrative abilities and the high state of efficiency to which he has brought the New South Wales railways.

The directors of the London Tramways Company, encouraged by the satisfactory financial results which have attended the working of their Brixton cable line, have just decided to extend their cable lines to Streatham. Messrs. Dick, Kerr, and Co., have been entrusted with the carrying out of the work, which, it is anticipated, will be finished by next summer. When completed this line will be able to give a car every one and a-half minutes.

The London and North-Western Railway Company is said to contemplate extensive alterations at Crewe Station, the traffic through Crewe both north and south having for many years been so great, that considerable trouble has been experienced in adequately dealing with it. The scheme of extension suggested involves the removal of the large steam sheds from the north to the south side of the station, and the removal of the goods warehouse from the south side to near the existing site of the steam sheds.

The subject of continuing the Los Angeles and Independence Railway from Los Angeles to Independence, in Inyo county, is again under discussion. A company has been formed for the purpose, and it is probable that a railway will be constructed from Los Angeles to the Ouens Valley, Inyo county, if bonds to cover the cost can be sold in England. The British Vice-Consul at Los Angeles observes as to this, "that it is a mistake for the British public to subscribe for American railway bonds, when the whole cost of the enterprise is to be paid out of the money realised on the sale of such bonds."

The French and Spanish Governments have agreed upon the construction of two international railways crossing the frontier near the ports of Salou and Somport. The first is to start from Saint-Girons, in Arriège, ascend the Satat Valley and penetrate into Spain by Esterri de Anen, to terminate at Lerida; while the second will leave Oloron, in the Basses-Pyrénées, and form a junction at Zuera with the Barcelona and Saragossa line. An international station is to be built on each of the two slopes, and the two tunnels to be driven for each line will be from 7 to 8 kilos.—mean four and a-half miles—long. The works of the Oloron line, begun in Spain, must be completed in five years, and the duration of all the works is limited to ten years from the ratification of the convention.

According to the *Schweizerische Bauzeitung*, on five principal Swiss Railways, namely, the Central, the St. Gothard, the North Eastern, the Jena-Simplon and the United Swiss roads, the proportions of metal and wooden ways are as follows:—Metal ties, Central, 60·1; St. Gothard, 57·7; North-Eastern, 39·8; Jena-Simplon, 33 1; United Swiss roads, 17·9. Wooden ties, Central, 39 9; St. Gothard, 42 3; North-Eastern, 60·2; Jena-Simplon, 66·9; United Swiss roads, 82·1. Steel rails, Central, 65 9; St. Gothard, 95·1; North-Eastern, 73 9; Jena-Simplon, 72 4; United Swiss roads, 75·7. Iron rails, Central, 34·1; St. Gothard, 4 9; North-Eastern, 26·1; Jena-Simplon, 27 6; United Swiss roads, 24·3. On the smaller lines metal sleepers are used less extensively, although on some of them they have found much favour, especially on the various rack railways, on which they are employed almost to the exclusion of wooden ones.

According to the Austrian *Eisenbahn Zeitung*, Herr Lochner, of the Royal German Railroad Commission at Erfurt, has carried out a series of trials with two locomotives of exactly the same design and construction, except that one of them had two equal-sized cylinders, 430mm.—17·2in.—in diameter, working as a simple engine, while the other worked as a compound with a high-pressure cylinder 440 mm.—17 6in.—and a low-pressure cylinder 660 mm.—26·4in—in diameter. The trials showed that the compound locomotives gave better results in point of steam and coal consumption only when the grades and other working conditions permitted of running at speeds of over 40 kilom.—24·8—an hour. With increasing speed there was a steady increase of economy. With speeds below the above figure, on the other hand, the simple locomotive showed the better results. All the working conditions were exactly the same in the two sets of trials, and were considered to be favourable, rather than otherwise, to the compound engine, so that under average conditions the latter would probably have shown a less satisfactory performance. The choice of engine, therefore, whether simple or compound, should, the *Railroad Gazette* says, and Herr Lochner concludes, be made to depend largely upon the ruling traffic conditions and character of the service for which the locomotive is intended.

The present Pacific terminus of the Great Northern Railway, crossing the State of Washington from east to west, is Seattle, on Puget Sound. Since its completion in February last, this line has obtained a good share both of the transcontinental and Western traffic. As the line extends its feeders into the agricultural and mineral districts, very gratifying results may be expected both for the company and State. All the transcontinental lines—the Canadian Pacific, the Great Northern, the Northern Pacific, and the Union Pacific—have now traffic arrangements by which both goods and passengers can be brought through from Eastern points to Puget Sound without changing carriages. Goods rates from and to Eastern points have been considerably reduced, which stimulated the development of the resources of the State, as well as shipping them to other ports, and consequently extending trade. Very little has been done recently by the various railway companies in extending branches, economy being the first thing considered. Most of the lines have reduced their expenses to a minimum by lessening the number of employés, and lowering the scale of wages. The miles of rail laid in the State are 2823. The gross earnings of the Oregon Improvement Company—a State railway—for 1893 were £775,549, against £778,416 for 1892. The net earnings during the same years were £144,785 and £152,567 respectively. Although there was not any serious accident in the State, heavy delays occurred on many of the lines through washouts, landslips, and blockades from the snow storms in the mountain passes.

## NOTES AND MEMORANDA.

A useful drip for turning steel can be composed of petroleum two parts and turpentine one part.

Sulphuric acid can be concentrated electrically by means of heaters consisting of coils of platinum wire suspended in the acid, through which a current is passed.

A method of obtaining nitric acid from the nitrogen in the air by an electric process based on the action of ozone has, according to Dr. Froelich, been discovered, and will shortly be described.

At a depth of about 45ft. the temperature of the earth in these regions is uniform throughout the year. This isothermal zone is variable as to depth through great ranges in different countries and parts of the same country.

We read that a poor quality of coal which is found in a certain mine in Germany, and which is too poor to be transported to any distance, is made use of by the erection of a large electro-chemical factory next to the mines, in which chlorine and soda are manufactured by an electrical process.

An improved gunpowder recently patented by A. Schindler, of Breslau, consists of 12 parts by weight of potassium chlorate, 3 parts of sugar, and 5 parts of anthracite, all finely ground and mixed. It is stated that anthracite, being denser and less easily combustible than ordinary charcoal, prevents the chlorate powder made in the way described from being too rapid in its action.

An artificial paving block which has been tried in Munich is, according to the *Gesundheits-Ingenieur*, composed of finely ground serpentine, compacted together with a small quantity of binding material, the process being patented. It is moulded into blocks and fired in porcelain kilns at a high temperature to a state of incipient fusion. Each block is 4in. by 7in. by 7in. and can be used on all four faces. The price of the pavement is stated to be about 16s. a yard, and it is said to have been laid in Hamburg as well as Munich.

Recent Washington despatches have mentioned a test of aluminium in salt water, just finished by the Navy Department. Two sheets were immersed for three months at the Norfolk Navy Yard; one was of pure aluminium, the other alloyed with a small percentage of nickel. The plate of pure metal was thickly covered with barnacles, and more or less corroded. The alloyed plate was covered with smaller barnacles, and very badly corroded. It is said that the officers of the Navy decided that aluminium could not be used where it would be immersed in salt water for considerable time. On the other hand, the accounts of the aluminium torpedo boat, recently built by Yarrow and Co. for the French Government, say that the tests of the Admiralty were very favourable. Before the building of the boat commenced Mr. Yarrow had two plates accurately weighed, then secured to the sides of a wooden, coppered sailing ship, the copper being removed and replaced by the aluminium. This ship made a voyage around the world, then the aluminium plates were removed, weighed, and found to have suffered no appreciable loss. Nothing is said, however, about the barnacles.

The meetings of the Manchester Geological Society are usually devoted to the discussion of questions interesting to mining engineers, but their meeting on Tuesday was devoted entirely to purely geological subjects, and evolved what was rather an amusing geological puzzle. Amongst the papers was one on "A new Species of Prolecanites from the Carboniferous Limestones of Haw Bank Tunnel, Skipton, Yorkshire," and Professor Boyd-Dawkins, F.R.S., wished to be informed as to the exact meaning of the term "prolecanites." The reader of the paper expressed his inability to give any explanation as to the precise meaning of the term; but added, that Professor Hyatt and Professor Zettall were the authorities for its use in the paper. The President, Mr. W. Watts, F.G.S., remarked that he had spent considerable time in consulting all the books he thought would bear upon the subject, with a view of finding some elucidation of the meaning of this term—but without success; and Professor Dawkins intimated that he would himself write to Professor Hyatt, and ask that gentleman to give a precise definition of the term he had applied to this new geological species.

As our readers are aware, efforts have recently been made in France with the object of reducing air resistance to engines by means of cut air or taper fronts, after the manner of the experiments of many years ago, and those by M. Ricour in 1887. In these, inclined planes were placed in front of the engine, and by adopting this means, making the slanting planes four in three, and filling up the spokes of the wheels, the resistance was, it was said, diminished by one-half, but this is absolutely contrary to previous experience. This resulted in a notable increase of useful work, and an economy of 10 per cent. on the coal consumption. The results are so satisfactory that M. Ricour has fitted his apparatus on forty engines belonging to the Paris-Lyon-Mediterranée Railway, for general traffic. Similar experiments were carried out in 1890 by M. Dresdouit, chief engineer to the State railways, and they were of more prolonged character. The engines were run in this case 300,000 kilometres, and by means of this apparatus they saved 6 per cent. to 8 per cent. in coal consumption, and sometimes as high as 12 per cent. M. Max de Souty tells us, however, "il est vrai que le chauffer et le mécanicien étaient excellents." A few other experiments were tried with seemingly the same satisfactory results. The main point, however, that on an average a benefit of 4 per cent. to 5 per cent. is obtained by the use of these inclined planes, and it is asserted that this is more than the saving obtained from locomotives with compound and other systems. Perhaps the results after a month or two of running would be better than short runs which do not take in flange friction from side winds on heavy days.

A paper by Professor S. P. Thompson and Mr. Miles Walker, on "Mirrors of Magnetism," was read at a recent meeting of the Physical Society. It was pointed out that corresponding to the theory of electric images produced by insulated conductors, there is a theory of magnetic images produced by bodies of infinite magnetic permeability. A magnet pole in the latter theory is the analogue of an electric charge in the former, and a body of infinite magnetic permeability is the analogue of an insulated conductor—which is electrostatically indistinguishable from a body of infinite dielectric capacity. Experiments were made to determine how far the magnetic images due to thick sheets of iron accorded with those deduced by theory for the case of infinite permeability. The image of a north pole in an infinite plane sheet should consist of a south pole of the same strength at a point coinciding with the optical image of the north pole, together with an equal north pole distributed uniformly over the surface of the infinite sheet, as a free electric charge would be, and exerting no finite action. Working at distances of a few inches in front of the surface, a plate of iron a few feet in length and breadth, and a couple of inches thick was found to realise the theoretical conditions with very tolerable exactness. In a coil of wire placed on one side of the sheet a current was started or stopped, and the electro-motive impulse produced in a subsidiary exploring coil was detected by means of a ballistic galvanometer. That the effect of the actual mirror was equivalent to that of the theoretical image was verified by substituting for the iron a coil equal and similar to the first, and coinciding with its optical image. Sending the same primary current as before round the two coils—with due regard to its direction in the second coil—hardly any appreciable difference in the secondary impulse was observed. This was found to hold good whether the original primary coil had its axis perpendicular or oblique to the plane of the magnetic mirror. Some observations on spherical sheets were also recorded, but in this case the conclusions were less simple.

## MISCELLANEA.

Large works are to be erected in the neighbourhood of Oldbury for the production of cyanide of potassium at a much reduced cost.

On a recent contractor's trial of the engines of the torpedo-boat destroyer Shark, in the Clyde, some of the copper tubes of the water-tube boilers split, and in consequence six of the men were scalded, some seriously.

The Institution of Civil Engineers, under the presidency of Sir Robert Rawlinson, K.C.B., at the last meeting elected 8 members, 130 associate members, and 4 associates, besides which the Council reported that 102 students had been admitted this session.

A new cruiser is being built for the Russian Volunteer Fleet by Messrs. R. W. Hawthorn, Leslie, and Co., of Newcastle-on-Tyne. She is about 500ft. long, 54ft. broad, with a draught of 24ft. It is stipulated that the speed shall average 19 5 knots during a twelve hours' trial.

The Bordeaux Chamber of Commerce have received offers from the Compagnie Française pour l'Exploitation des Procédés Thomson-Houston, Messrs. Guilton and Bertolus, of St. Etienne, and Messrs. Lombard, Gérin, et Cie. for the supply of electric cranes for the quays of that city.

The United States torpedo-boat Ericsson again broke down undergoing her official trials on Nov. 22nd. The contract speed is 24 knots, and the vessel was making 23 knots when the accident occurred, viz., the breakdown of the starboard air-pump. This is the fourth time her official trials have had to be abandoned.

Countess Spencer has undertaken to perform the ceremony of naming the new barbette first-class battleship Magnificent, which is to be floated out at Chatham Dockyard on December 19th. The first keel plate was laid less than twelve months since, so that the building may be regarded as a remarkable feat in naval construction.

The Cunard Steamship Company is considering the advisability of sending its steamers from Southampton instead of Liverpool. Delays at Queenstown, the lack of direct railway connection with the docks at Liverpool, and the want of a deep-water landing pier at the same port are the causes stated for the proposed change of terminus.

Messrs. Weyman and Hitchcock have opened a London office at 11, Queen Victoria-street, E.C. This firm have recently moved into new and completely equipped works at Cheltenham, equal to an output of some 500 or more of their Trusty oil and gas engines per annum, and they have, we understand, perfected their launch engine.

H.M.S. Wild Swan, sloop, recently underwent a satisfactory trial, at Keyham, of a system of induced draught with which she has recently been fitted. The Martin system was used. The results of the trials of this system have so far shown a distinct economy as compared with the ordinary forced draught system, and other advantages are also secured by it.

A new type of Whitehead torpedo, especially adapted for dropping gear, is being introduced into her Majesty's Navy. Although its diameter is but 14in., it has proved itself to have all the advantages of the short 18in. type, with greater stability and a larger explosive charge, and will be admirably adapted for boat work and the armament of small cruisers. No more of the short 18in. are to be manufactured, and the first-class battleships now building, and the cruisers Powerful and Terrible, which it was intended should carry them for use with boats' dropping gear, will now be supplied with the new 14in. type.

The Lake Washington Canal Scheme, concerning which there has been considerable discussion in Seattle for a number of years back, is in a fair way to be carried out, according to the *Post-Intelligencer* of that city. This paper reports that a contract has been signed by the State Land Commissioner and Eugene Semple for the construction of the canal. The work is to commence not later than March 1st, 1895, and is to be completed in six years. The canal is to be of sufficient capacity to accommodate vessels 300ft. long, 75ft. beam, and 22ft. draught. The contractor is permitted to construct and operate locks on the canal and charge tolls until the Government takes charge of them under the provisions of the Act authorising the work.

The Right Hon. A. J. Mundella, M.P. for the Brightside Division of Sheffield, was on Tuesday, at the Cutlers' Hall, Sheffield, presented with several gifts in recognition of his services in trade and commerce, during his twenty-five years' representation of Sheffield in Parliament. The principal present was his own portrait by Mr. A. S. Cope, A.R.A., which Mr. Mundella passed to the Mayor to be hung in the new City Hall. A replica of the portrait was presented to Miss Mundella. The other gifts were a beautiful cabinet of cutlery, consisting of nearly 200 pieces, and three silver bowls, of excellent design, manufactured by Messrs. James Dixon and Sons, of Cornish-place. There were several hundred contributors, irrespective of politics and creed, and the amount subscribed was £700.

The French Société Technique seem to be a munificent body. The following prizes are now offered by them to persons of any nationality:—£400 for a markedly better incandescent gas lamp, to be sent in before April 1st, 1895, the Council to decide whether the time may not be extended to May 1st, 1896; £320 in various prizes for essays on any subjects affecting the gas industry, particularly on mechanical handling of coal, coke, &c., on water gas or revivification, or on the substitution of hydrocarbons for cannel; £80 between those who have made the greatest progress in apparatus for making or using gas. Papers to be in French, and unpublished; motto, with name in envelope, and a declaration inside that the paper is unpublished, and that the author will not publish otherwise for a year. To be sent to the Société, 65, Rue Provence, Paris, by the end of April next. Also prizes of £10 to the authors of the best papers at the annual meeting, provided in this case that they are members of the Société; and the usual prizes of £8 each to deserving workmen long under the same company, or in the same gasworks, without a break.

Concerning the French battleship Brennus, a correspondent, writing recently to the *Times*, says: "M. Marc Landry has written an interesting letter, which appears in the Paris *Figaro* of December 5th on the construction and failure of the Brennus. Her keel was laid on January 2nd, 1889, at Lorient; she was launched on October 17th, 1891, and has since that date been in the hands of the dockyard. Early in this summer she did her speed trial, and made good 16½ knots, a full knot less than her calculated speed. This autumn she was tested for gun fittings and stability, and is now to be largely reconstructed; when the guns are all trained on one side, as would probably have to be done at some period of an action, she listed so much that the hydraulic gear for working the guns was useless. The Brennus is a first-class battleship of 11,000 tons, designed to carry three 58-ton guns, ten 7-ton quick-firing guns, and twenty minor pieces. Her cost is already £1,200,000, and the contemplated alterations entail a further large expenditure. The excess of the top weights on the ship over the estimated weights has been caused by alterations made during construction. In our dockyards the comparative rapidity with which the warships are completed tends to lessen this mismanagement, but it is to be feared that pressure has been brought to bear on the construction department lately, which has caused expensive alterations of doubtful value to several of the already completed second-class cruisers."

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

A. H. W.—*The reel in your sketch simply takes the place of the pedals. The bicycle will move in the direction of the pull.*

E. du B.—*Small screw moorings are perfectly satisfactory if properly put down. They can be obtained to order from almost any ironfounder in a large seaport town.*

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*
*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

The Institution of Civil Engineers.—Tuesday, December 18th, at 8 p.m. Paper: "Colliery Surface Works," by Mr. Edward B. Wain, A.M. Inst C.E.

The Newcastle-upon-Tyne Association of Students of the Institution of Civil Engineers.—Wednesday, December 19th, at 7 p.m. Paper: "Newburn Bridge," will bé read by J. H. Barker, A.M. Inst. C.E.

The Institution of Junior Engineers.—Saturday, December 15th. Visit to Hampton Station of the Southwark and Vauxhall, Grand Junction, and West Middlesex Waterworks. Train leaves Waterloo at 2.15 p.m.

Cleveland Institution of Engineers.—Monday, December 17th, at 7.30 p.m. precisely. Paper: "On Economy in Steam Raising," by Mr. T. F. Meldrum, Manchester.

Royal Meteorological Society.—Wednesday, December 19th, at 7.30 p.m. Papers: "Report of the International Committee on the Cloud Atlas," by Robert H. Scott, M.A., F.R.S.; "Rainfall and Floods in the Catchment Basins of the Severn, Wye, and Usk, November 1894," by Henry Southall, F.R. Met. Soc; "Meteorological Observations at Mojanga, Madagascar, 1852-1894," by S. C. Knott.

Liverpool Engineering Society.—Wednesday, December 19th, at 8 p.m. Paper: "The Second Law of Thermo-dynamics," by Professor Oliver J. Lodge, D.Sc., LL.D., F.R.S.

Society of Arts.—Monday, December 17th, at 8 p.m. Cantor Lectures: "Modern Developments in Explosives," by Professor Vivian B. Lewes. Wednesday, December 19th, at 8 p.m. "Forestry," by General J. Michael, C.S.I. Clements Markham, C.B., F.R.S., P.R.G.S. will preside.

Aeronautical Society of Great Britain.—Saturday, December 15th, at 3 p.m. Reading and discussion of papers.

# THE ENGINEER.

*DECEMBER* 14, 1894.

### THE MACHINERY OF WARSHIPS.

We have already directed attention to some of the features of the paper which was read by Mr. A. J. Durston at the Institution of Civil Engineers on the 20th ult., but much remains to be said. As we have before stated, it was one of the most important of the marine engineering papers which have been contributed either to the Institution or to kindred societies. We regret that the discussion on it was hardly so full and complete as the subject deserved; indeed, some points of special interest in connection with warship machinery were passed over altogether. The paper itself is a statement of accomplished facts. Some particulars of the engines and boilers of 133 of the most recent war vessels are given, these including the whole of the seventy vessels built under the Naval Defence Act of 1889, and those vessels constructed during the few years immediately preceding the passing of that Act. Although the tables given look to be imposing with their large array of figures, it will be found by anyone who searches them for data upon which to base new designs, that practically no information can be got from them beyond the actual indicated horse-power obtained on trial trips, the total weight allotted to machinery, and the grate and heating surfaces of the boilers. The precise weights of boilers alone cannot be arrived at, as the weights given include, besides the boilers and their accessories, all casings, spare gear, and fittings in the boiler rooms; quantities which may vary with different designs and different arrangements. The other figures of the tables can be obtained from those already quoted.

We see from the paper that the period over which the building of the vessels extended embraced that marked by the important changes in design due to the substitution of the triple expansion engine for the two-cylinder compounds, and to the use of vertical in preference to horizontal engines. With the later designs the piston speed has been increased to 918ft. per minute, as compared with about 750ft. in the older vessels, while at the same time a considerable increase has been obtained in the power realised in proportion to the weight, in the way pointed out in our last impression. Especially is this true as regards the natural draught power. There is no doubt, also, that the more recent types of engines are more economical in coal consumption than those previously used, so that an all-round advance has been obtained.

It is not so much, however, with the information given in this paper that we are at present concerned, as with that which has been withheld or only briefly referred to. The Institution of Civil Engineers is a widely representative body, and amongst its marine engineering members the majority have not an intimate knowledge of the special requirements of the machinery of warships, and are therefore likely to judge of the particulars given, and the performances quoted, from the special standpoint of their own experience, which has been gained mainly or entirely with machinery of merchant vessels, in which the requirements are totally different. We think, therefore, that Mr. Durston would have done well, in placing a paper before this Institution, to have drawn attention to the very different requirements of the machinery in ordinary merchant vessels—where only one power, the full power, has to be provided for, and where economy at that power is of far greater importance than any question of weight or space which is likely to arise—from those of engines of warships in general, where not only is the production of a large power in proportion to weight an important consideration, but where the engines have to be so designed as to be as economical as possible at various rates of power, from the very highest to the very lowest. It would also have added much to the value of the paper if he had briefly indicated those special points which have determined differences of proportions of machinery under apparently similar conditions. As illustrating this, we may draw attention to the cases of the battleships Royal Sovereign and her sisters, and the Barfleur and Centurion. In each case the maximum power originally intended to be obtained was 13,000. In the former vessels a ratio of low to high-pressure cylinders of 4·84 to 1 was adopted, while in the two latter the proportion was 5·37 to 1; yet in the case of the latter, which presumably should be the more economical engines, the heating surfaces of the boilers exceeded those of the others by more than 10 per cent. A somewhat similar difference exists in comparing the machinery of the first-named battleships with that of the first-class cruisers. In the latter the cylinders are of identical dimensions with those of the former; but, instead of 13,000 indicated horse-power to be obtained, only 12,000 was attempted, and, to produce the lower power, boilers nearly 25 per cent. larger were provided. The proportion of power to heating surfaces in the battleships was thus nearly one-third more than in the cruisers. We do not question the wisdom of the Admiralty in adopting such differences of proportion; but we think that, without some explanation of the varied requirements of the two classes of vessels, very erroneous opinions may be formed on the subject.

Another very important point, to which attention was drawn by Sir Edward Reed, is the small amount of information given as to the reason why some of the battleships and first-class cruisers were not submitted to the ordinary full power or forced draught trials. The battleships were originally intended to indicate 9000 indicated horse-power at natural draught and 13,000 at forced draught. They all developed considerably over 9000 at the natural draught trials, but only one—the Royal Sovereign—was tested to the full power of 13,000, the average power obtained by the other seven vessels being only 11,500. In the case of the nine first-class cruisers the natural draught power was intended to be 10,000, and the forced draught 12,000. While all of them were tried at natural draught and successfully obtained the 10,000 horse-power expected, only three of them were subjected to the forced draught power trials. All that Mr. Durston tells us regarding this is that the valve gears were arranged for a maximum of 11,090 and 10,000 horse-power in the two classes of vessel, to enable them to steam more economically at the low powers usual when cruising. We are told also that the higher powers originally contemplated could at any time be developed by suitable modifications in the valve-gearing and propellers. On the face of it, this does not seem to us to be altogether satisfactory. We now learn that the leaky boiler tube question has been reduced to one of an insignificant character. Somehow or other the impression exists that this question had no little influence in determining the reduction of power referred to above, and if the trouble has been got over, by means other than the reduction of the power expected out of relatively small boilers, it appears to us that the full powers should now be obtained from these vessels, instead of our being contented with the reduced powers. If the less power is sufficient for all the needs of these ships, why was machinery of greater weight and cost than necessary placed in them? If, however, the present reduced power is the maximum which can with safety be obtained from the machinery as fitted, the fact should be fully recognised.

The impression that the leaky-boiler tube question helped largely to determine the reduction of power we are considering becomes strengthened when we look at the proportions between powers obtained and weights of boilers. In the Admiral class, where very little trouble was experienced from this cause, we find that 169 indicated horse-power was obtained per ton of boiler. These vessels were fitted with compound engines and only worked at 90 lb. pressure. Allowing that triple expansion engines are 20 per cent. more economical in use of steam than compounds, if the boilers of the later vessels were only forced to the same extent as those of the Admirals, and making no allowance whatever for the increased weight due to strength requirements for the higher pressures used, we should get 20·3 horse-power to the ton; but, allowing for the increased weight due to the strength requirements, somewhat less should be expected. In the Australia and her sisters 20·7 was actually obtained. In the third-class cruisers of the "M" type 25·3 horse-power per ton was realised; while in the Blenheim no less than 28·3 was developed. In the battleships at the reduced powers of 11,500, only 19·7 was obtained, while in the first-class cruisers at their reduced power the figures fall to 16·2. It is very significant that the leaky tube troubles increased as the power per ton increased, while with the considerable reduction in this proportion all trouble from this cause vanishes.

In reply to the discussion on his paper the author explained that, as an average, taking the so-called natural-draught power of war vessels to represent 100, the forced draught or full power would be about 120, while the actual full power expected to be maintained at sea continuously for long periods would be from 60 to 80. Remembering that the so-called natural draught power is really obtained with closed stokeholds, using ½in. air pressure in cases where ordinary boilers are used, and as much as 1in. where the boilers are of the locomotive type; it will be seen that the power which should really be called the natural draught power, and which can fairly be compared with that obtained in merchant vessels, is neither the forced draught nor the so-called natural draught power, but the power represented by the 60 to 80. In other words, it is only about one-half of the forced draught or full power. In comparing the machinery of war vessels with that of merchant vessels this should be borne in mind, and we think that the author would have done well to have pointed it out. Unless this is borne in mind by those who are familiar with the performances of our splendid mail boats, such as the Campania or Caledonia, which during their whole voyage of many days' work at full power, without any stoppage whatever, and this not once or twice only, but continuously and regularly, the statements of the Royal Sovereign, of nominally 13,000-horse power, maintaining 8180-horse power for seventy-two hours, or of the Sirius, of 9000-horse power, maintaining 4555-horse power for sixty-four hours, would appear to be condemnatory of these vessels, instead of being, as they really are, of a satisfactory character. The coal consumptions quoted are also liable to be misconstrued, if compared with those obtained with machinery designed specially with a view to economy, unless the special conditions dominating the designs are remembered.

The omissions of the explanations we have indicated are, however, in our opinion, not so important as the total silence regarding the reasons which have led the Admiralty to adopt the Belleville boiler for the new cruisers Powerful and Terrible in preference both to ordinary boilers and to water-tube boilers of other designs. We do not for one moment doubt that the Admiralty had good reasons for the course they have pursued; but at a time when marine engineers throughout the country, and shipowners as well, are anxiously looking for light and leading on the water-tube boiler question, any statement of the facts upon which the Admiralty must have based their decision to adopt this special type of boiler would have been extremely welcome. The choice of a type of boiler is no light matter. A mistake in this respect will be fatal to the success of almost any vessel, and it is not too much to say that information on this point was eagerly looked for, and the disappointment at its not being forthcoming is keen. It was also anticipated that some data would have been vouchsafed as to the evaporative efficiency of these boilers as determined by the experiments which have been made on the Sharpshooter. All we are told is that the boilers have given satisfaction. Surely here a great chance of obtaining the gratitude of engineers and shipowners in general has been missed.

There is one point raised by the paper which, although no reference was made to it in the discussion, gives us great concern. It is not so much to do with the machinery as with the men. We gather from Mr. Durston's paper that the only training our engineer officers and engine-room staffs have, when in commission, for using the powerful machinery fitted on board at anywhere near its full power, is limited to a four-hours' trial once in *three months* at the natural draught power, while the forced draught power is never obtained, or even attempted. This we consider is a very grave matter. It goes without saying that speeds and powers obtained once on the official trial trips are of no use whatever, unless they can be obtained when required, as emergencies arise, by the vessel's own staff. It is common knowledge that even on the trial trips, where the contractors employ as large a staff as they please of highly-trained men, from some reason or other the trials are sometimes unsuccessful, and it cannot be expected that such powers and speeds can be attained by the ordinary crews with certainty and safety unless they have special training at these powers. We hope that a similar course is not pursued of only occasionally training our gunners and torpedo staff with blank charges and with dummy torpedoes. This question of properly training our engine-room staff is of the utmost importance, and must be faced at once. It is more than ever necessary now that quite a fleet of destroyers is being added to the Navy. The engine department of these vessels is a complete departure from everything which has preceded them, and their wonderfully light and powerful machinery can only be properly utilised by training a sufficient number of engineer officers, artificers, and stokers in their use, not only at comparatively low powers but also at full power. We hope that the Admiralty will do this, otherwise when the time arrives for their use in actual warfare we shall find that they will have to be kept in harbour because we have no one who can properly keep them at sea.

### FACE-HARDENED ARMOUR IN THE UNITED STATES.

Captain Sampson, U.S.N., Chief of the Bureau of Ordnance, has contributed a paper to the American Society of Naval Architects on the "Present Status of Face-hardened Armour." The position of the author and the importance of American investigation in this question give special weight to this paper. The author states that although the shrinkage and change of angles in the various processes of cementation and tempering involved in face hardening, complicated by those of bending and rectification, seem to follow no definite law, still manufacturers have succeeded in foreseeing them with sufficient clearness to make most satisfactory butts and joints in the armoured structures thus far inspected. "The difficulty of securing structures to the hard face, in default of knowledge as to the exact location of the fastenings, is also in course of solution. It was found feasible to tap and drill holes in the face of the plate at any stage of the process prior to hardening without detracting from the plate's resistance; but as it was impossible to locate these holes with precision without fitting the armour into place, this method was abandoned in favour of one by which the carbon was prevented from penetrating over certain areas in the wake of the fastenings. This method had also its disadvantages, in that the carbon gases frequently seeped through the protecting material and carbonised the surface beneath. The most satisfactory method, and one which will probably be employed in the future, is that of electrically annealing the surface to be drilled." We have quoted verbatim those sentences which deal with the pith of the manufacturing question. It is curious to observe that for the moment the makers in the United States and England are moving in opposite directions in more than one respect. We say in England nickel treated plates cannot be acted on by the arc drill, and those plates which have no nickel in them are, after all, best dealt with by drilling holes before face hardening. On one occasion Brown's firm have submitted a plate with a soft margin to take drilled holes, but it was rather regarded as a possible than likely expedient. In the United States, on the other hand, soft places or holes drilled before hardening have been tried and superseded by the electric arc drill, and that with nickel Harveyed plates, which we consider do not admit of its application. Further experience must modify such sharp contradictions.

Captain Sampson considers that the greatest objection to face hardening, and the one likely to continue, is cost. Repeated machinery and other operations can hardly be dispensed with, which must involve expense. As to nickel, Captain Sampson speaks strongly in its favour. It enables armour to be made "far stronger and more resisting," and at the same same time tougher also. When its working has been mastered, its use diminishes risk of failure, because it is less susceptible to injury in working, though very susceptible to treatment. Hence the decreased percentage of failures will go far to wipe out the increased cost of machinery. "Nickel also appears to render the carbon more sensitive to hardening, and hence water-hardened Harvey plates of nickel steel are toughened at depths hardly affected in simple steel plates." The difficulties mentioned by Mr. Ellis have hardly been experienced in the United States. In short, the question now is, whether the present percentage of nickel, 3·25, cannot be increased. Captain Sampson states that the Witkowitz unhardened plate, which won the remarkable victory at Pole over treated competitors, contained 5 per cent. of nickel. Even in England, says the author, nickel steel is employed for unbacked structures. A word or two is called for here. We do not know what is referred to. Horizontal armour has been made of nickel steel in England, but it has been rejected, we believe, for all side armour. Personally we so far go with Captain Sampson that we hope that the final word on nickel has not been spoken in this country. We have held that we could not afford to let nickel drop, seeing that for shields which are exposed to an attack which is formidable from its long continuance, and not from the crushing force of a single blow, nickel steel is the best possible material speaking from present knowledge. An inland cupola or shield, for example, would be exposed to the long-continued breaching attack of siege guns of moderate power. It would be easy generally to supply an untreated nickel shield, capable of resisting a single blow, and such a shield would bear continued attack indefinitely long. It would, it fact, behave like a very superior kind of wrought iron. Further, without questioning the wisdom of supplying for our ships building at the moment the shields which we find best, namely, treated steel without nickel, we trust that nickel is not to be lost sight of, even for ships, as still possibly desirable. The experience in America deserves to carry weight enough to forbid our disregarding it. A competition between a champion treated nickel United States plate and an English all steel one would be specially valuable, and we think that he would be a bold man who would back the all steel plate confidently.

We need not follow Captain Sampson into the details of the conditions of French and United States plate tests. He sums up the firms who have adopted the Harvey process as follows:—In England, Cammel, Brown, and Vickers; in France, St. Chamond, Chatillon-Commentry, Marrel Frères, and St. Etienne, and Messrs. Schneider; also Krupp, Dillinger, and Witkowitz, although the five last-named had face-hardening processes of their own. Although the author considers that it is rather wild work to estimate the amount of increased resisting power due to Harvey's process, the French estimate of 1·8 and the English of 1·83, as compared with the same thickness of wrought iron, agree. Probably the case, when the same relation in America worked out as 2·14, is exceptional. The fact, however, is that any thoughtful man would, like Captain Sampson, refuse to be drawn into an exact estimate, seeing that the resistance of treated plates depends on their power to fracture the shot. How can the power of a breaking tool be a matter of close calculation? Further, could this even be done, circumstances may arise when the shot does not break, and when the conditions are consequently wholly changed, as in the case of occasional rounds fired at low velocities, or with caps on the point of the shot. On this last question the author expresses the opinion that the cap does not prevent fracture proper, but rather acts as a sort of lubricant or medium, on which the jagged edges of plate work, instead of gashing into the steel shot itself. As to this, while it is certainly true that capped shot, after obtaining much greater penetration than others, are often found broken, the explanation readily suggests itself that fracture was deferred till considerable work was done. As to Captain Sampson's objection that the metal of the wrought iron cap had not been found on the face of the plate, and therefore could not have worked back and formed a support round the shot head, we must remember that it is the hard skin alone which fractures the shot of the present day; the needed pad or support to help the tip of the shot through this is a very small one, the cap on the lower part of the head may act perhaps as Captain Sampson suggests. Judging from the tables, the cap has been rather less successful in America than in Russia and England, which accords with the author's belief that the hard film extends deeper in nickel than in plain steel armour. Captain Sampson concludes with the sound opinion that, let projectiles improve as they may, it must always be advantageous to harden the face of a plate.

Captain Jaques, in discussion, questioned the adoption of Harvey's process by all those who had other hardening processes of their own. He thought it difficult to accept England's conclusion that while the United States had led the way with treated armour, it was safe on the results obtained in England to throw over nickel, which has been found so valuable in America as well as by Krupp and St. Chamond. Captain Jaques' remark as to the English experience of treated plates being principally confined to 10·5in., and in a great measure to 6in. plates, bears upon the question of nickel, we think, holding as we do that hardness has its greatest value in the thin plates used for cruisers, while toughness grows in relative value in line-of-battle ships, attaining, as we have already said, its minimum value in inland shields. Captain Jaques made some allusion to the efficiency shown by the Japanese. It appears that he has rendered such assistance to Japan in the ordering of their armaments as to receive the decoration of the Rising Sun, a very significant decoration for an ambitious Eastern Power.

### EMPLOYERS AND THE UNEMPLOYED.

Manufacturers in the North and the Midlands are turning their attention more and more to the question of relief for workmen out of employment, as well as for those who are incapacitated by advancing years or sudden accident. In several districts a system of old-age pensions has been adopted. In Sheffield some of these organisations are now, and have been for some years, in active operation. It has been felt, however, that these are not quite adequate to meet the increasing requirements of our various industries. One of the leading manufacturers, Mr. Joseph Jonas, J.P., of the firm of Messrs. Jonas and Colver, Continental Steel Works, Attercliffe, has brought before the notice of the working men in that district a method which he found in operation in Berne, a Swiss town, with a population of between 35,000 to 40,000. Since April of last year there has existed at Berne an association, supported and subsidised by the Corporation, to insure members against unmerited loss of employment. Every member contributes 4½d. per month to the general fund, from which relief can only be had during the hard winter months of December, January, and February. No contributions are levied upon members when they are out of work. After a period of at least six months' membership, the unemployed can apply for employment or relief. If the committee fails to provide work to any member, he is entitled to a payment out of the Society's funds of 9½d. per day if single, and 1s. 2d. per day if married. The claim to the Society's benefits is forfeited if employment should have been lost through illness, drink, immorality, disobedience, or other bad conduct. It is also also provided that the relief fund shall not be available for those who give up their calling in consequence of wages' disputes or strikes. The fund, it may be mentioned, is maintained from four sources—(1) by the contribution of the members; (2) by contribution of the employers; (3) by subsidies from the Corporation; (4) by voluntary subscription. The subsidies voted by the Corporation are to supply any deficiency at the end of each financial year, the total amount not exceeding £200. The Committee of Management consists of seven members, of whom three are elected by the Town Council, two by the members entitled to the Society's benefits, and two by the contributory employers. These seven elect their own chairman. In December, 1893, the number of unemployed members who made application for relief was 118; in January and February, 1894, ninety-two and six respectively. Of this number, 216, the committee provided fifty with work, and the remaining applicants received £270, or an average of about £1 12s. 6d. each. The Corporation, to meet these claims, had to make up a deficiency of £190. Mr. Jonas does not think that the system has been in operation long enough to recommend its immediate application to England, but he points out that some properly organised insurance against loss of employment is a great aid to the authorities in dealing with the unemployed, whose numbers, in times of trade depression, often increase to a degree of general calamity. "Such institutions," he says, "enable them to distinguish and to refer to those of the unemployed, who have still some sense of the principle of self-help, and are ready to bear some sacrifice to that end." The Berne scheme is, of course, but an experiment, and the fact that £190 had to be provided by the Corporation out of a total of £270 is rather formidable when it is faced. Applied to our great cities, with their hundreds of thousands of people, the drain upon the municipal resources would in proportion be serious. But it is serious in any case. The difference between the present methods of relief, or to put it more accurately, the present want of method, and an organised scheme like that at Berne, is simply that in the first case the money is given almost haphazard, and relief works, which are inevitably resorted to, are costlier even than charity. This is inevitable, for men accustomed to a craft requiring delicate handling are suddenly set to road-making, or excavating, or street clearing, or some other rough occupations, for which they are utterly incapable. In the scheme explained by Mr. Jonas, on the other hand, there is the element of discretion and the recognition of the principle of self-help. There is no doubt that once a community recognises the right of people who are out of employment, through no fault of their own, to consideration at the public hands, that community will take the utmost care that the number of unemployed shall be reduced as low as possible. Friendly Societies can undoubtedly do a great deal in this direction, and the Berne scheme appears to point out a way in which their utility could be vastly extended. The discussion at all events of this, or any other such scheme, is decidedly helpful for arriving at a clear knowledge of the best means of meeting the great emergency of thousands of people without anything to do, and a whole community at its wits' end to give them sufficient to keep body and soul together.

## LITERATURE.

*Ways and Works in India: being an Account of the Public Works in that Country from the Earliest Times up to the Present Day.* By C. W. Macgeorge, M.I.C.E. London: Archibald Constable and Co. 1894.

The field that, according to his title, the author enters on is wide and interesting. He tells us at starting that his facts and figures have been mainly gathered from official publications, Government records, and reports or papers read before the Institute of Civil Engineers. He has, however, compiled a very readable volume, and has treated his subject so as to be useful to the student, while it interests the general reader. Although with much to approve, we must take exception to the introduction of much superfluous matter, such as expositions of the elementary principles of trigonometrical surveying and telegraphy, and the unnecessary references to English examples and practice in the case of railways. Even a tyro in engineering can hardly care to have served up in connection with Indian railways the oft-told tale of the Rocket, &c., and the history of the rise of the English railway locomotive system under Robert Stephenson, or the Board of Trade regulations. The book, however, when it comes to deal with the facts and descriptions of actual works, is at its best, and the reader is rewarded by the value and interest of the matters treated of. He traces up the road system of India from the time when roads were mere tracks or avenues for the use of foot passengers and pack animals, with a covering of soil only, to the condition when wheeled carriages demanded the improvement of the surface by moorum, gravel, kunker, or metal coverings.

His history of the introduction and development of railways in India is very full and interesting, and his selection of examples of works of construction on both roads and railways is very judicious, although in one or two cases, such, for instance, as the Kahan Bridge, we fancy, from rumours that have reached us, there remains more to be told. The subject of railways occupies more than one-third of the volume, and in the matter of statistics and finance, which he quotes in great detail, he brings us up to the end of the year 1891.

In India, next to railways, irrigation works are most important, and to this subject he devotes nine useful chapters, in which he sketches briefly the outlines of the more important works throughout the country. A few chapters on the water supply of towns, in which some useful information is collected, including the most recent additions to the supply of Bombay, Madras, Kurrachee, Jubbulpore, and elsewhere, disposes of this part of the subject. The book closes with articles on the electric telegraph system and the sea and harbour works of India, in which the information given regarding the very important works both in Bombay and Calcutta is meagre in the extreme. Some voluminous statistical tables and a good index, with a trigonometrical chart, complete this acceptable little volume.

*The Repair and Maintenance of Machinery.* By Thomas Walton Barber. Spon, London. 1894.

"Give a dog a bad name and hang him;" give a book an inappropriate title and it receives even more severe

IN THE ENGINE ROOM OF THE STEAMSHIP CALEDONIA—THE ELECTRIC LIGHT INSTALLATION

treatment. Parts of the work before us might have passed muster under another cover; had the book, for example, been called an "Illustrated and Descriptive Catalogue of Certain Machines," one might have received it, if not with approval at least with patience, but the former emotion is never inspired, and the latter virtue is soon exhausted when the reader finds on page after page of a work professing to be written for a specific purpose, only the most trivial matters in connection with its ostensible subject. An excerpt or two will satisfy our readers that the strictness of this censure is deserved. On page 18, in a chapter entitled "Boiler Repairs," we find an important operation disposed of thus: "In bad cases it becomes necessary to cut out a fire-box or flue tube entire, repair or replace it by a new one, and then rivet in again. Such an extensive repair is very costly, especially if executed on the spot." No word whatever occurs about the means generally adopted for effecting this renewal. A tailor could have told us nearly as much about patching a boiler as this engineer has to say. No examples that are not absurdly evident are given. The author catalogues and illustrates the defective parts well enough, but in a work of this nature one is led to expect remedies and not diagnoses only. Again, on page 56, Mr. Barber has under consideration a cylinder in which the admission port allows steam to blow through into the exhaust. To mend the defect he says, "If the hole can be got at in any way it may be plugged, or covered by a plate carefully let in by a good fitter." No sketches, no example, no suggestion as to overcoming difficulties, nothing but this bald unneeded suggestion. On the opposite page a sketch of an ill-proportioned piston ring catches the eye. The letterpress accompanying it gives very bad instructions. "Piston rings," the author says, "should be turned a little larger than the bore, so that when cut they have sufficient spring in them to fit tightly in the cylinder." Now-a-days a good engine builder splits the rings after rough turning, presses the sections close and finish turns them to the bore of the cylinder. A very little fitting then makes them touch evenly all round. Mr. Barber's ring would rub hard in three or four places perhaps, not being of the same curvature as his cylinder. It is quite unnecessary to multiply examples of the weakness of this work. As regards repair and maintenance it is practically useless—except, perhaps, to a totally inexperienced person. Regarded as a catalogue, the section devoted to gas engines is the most complete and useful, though even in this we find a serious omission. Atkinson's gas engine is not illustrated, and an indifferent description only is given. As this engine is unique in its action and among the most economical in its working, it deserved fairer treatment. Most other types are illustrated and explained. This part forms the only redeeming feature of the book.

We must ask the author, too, to forgive us for suggesting that even technical English has a grammar and syntax, and that "style" in an author is esteemed a desirable quality.

## *BOOKS RECEIVED.*

*The Royal Indian Engineering College, Cooper's Hill. Calendar for* 1894-5. Containing a syllabus of the courses of study. Price 5s. London: W. H. Allen and Co. 1894.

*Workshop Appliances.* By C. P. B. Shelley, M.I.C.E. Revised and enlarged. Tenth edition. London: Longmans, Green, and Co. 1894.—The value of this book has been considerably increased by the addition of a chapter on "Milling," by R. R. Lister.

*Model Engine Construction. With Practical Instructions to Artificers and Amateurs.* By J. Alexander. London: Whittaker and Co. 1894.—Usually amateurs and boy engineers have to be satisfied with very inferior drawings of engines and other machines of which they wish to make models, but in this book Mr. Alexander, aided by the drawings of Mr. C. E. Jones, has made things considerably easier for the model maker. We do not, however, see why so thick a book should be made by leading the type out to a most unnecessary width, no advantage being gained, as far as we can see, in any way.

*The Electro-Platers' Handbook: A Practical Manual for Amateurs and Young Students in Electro-Metallurgy.* With sixty-one Illustrations. By G. E. Bonney. Second Edition, enlarged by an Appendix on Electrotyping, &c. London: Whittaker and Co. 1894.—But few modifications have been made in this edition, and these only to meet small changes in the structure of apparatus which have been made since the publication of the first edition. Electro-plating in the various ways as described in this book can be easily carried out by the amateur, as well as by those who conduct these operations for business purposes, and it may provide a useful as well as an interesting leisure occupation.

*Building Construction: A Key to Examinations of the Science and Art Department.* By Henry Adams, M.I.C.E., F.S.I. London: Chapman and Hall. 1894.—Although the author of this book says there is no royal road to success in examinations of the Science and Art Department, the object of his series of books, of which this is one, is, as far as possible, to provide that royal road. It relates to the construction of walls, that is, bricklayers' work, bonding, &c., foundations, methods of building in beams and key-plates, excavating for foundations, the construction of roofs and of diagrams showing the stresses upon them, construction of windows, doors, framework, stairs, iron roofs, and the strength of beams and floors.

## FERDINAND DE LESSEPS.

On the 6th instant passed away at a great age Count Ferdinand de Lesseps, after a brief illness. His name will be linked for centuries to come with the greatest engineering success and the most disastrous engineering failure recorded in the history of nations. The Suez Canal virtually revolutionised the construction of the world, bringing the east and west together. The Panama Canal, had it been ever so successful as a canal, could not possibly have had a similar influence on the doings and dealings of mankind. The Suez Canal reduced the time occupied in traversing the interval between Europe and India, not alone for ships, but for mankind. But the Panama Canal could do the world no similar service, because already the railway unites the western and eastern coasts of the North American Continent. Happy would it have been for multitudes if Count de Lesseps had remained content with his achievements in Africa and left the New World to younger men.

De Lesseps was not only a Frenchman, he was a Parisian. The difference is important. He was born at Versailles on the 19th November, 1805, at a period when railways were unknown and steam did little else than pump. In no real sense of the word was De Lesseps an engineer. He was a diplomatist by birth, education, and instinct. He received his education at the expense of the State, at the Lycée Napoléon. In 1825 he was appointed as Attaché to the French Consulate at Lisbon, and in 1828 he was Attaché to the Consulate-General at Tunis. He went to Egypt in 1831, and became Consul at Cairo in 1833, and subsequently at Rotterdam, Malaga, and Barcelona he filled a similar post.

The history of the Suez Canal has been very fully narrated in our pages. To reproduce it here would serve no good purpose; rather let us sketch, however briefly, the career of the man. In 1841 he seems to have first thought of the project. Wars and rumours of war, the events in the Crimea, the Indian Mutiny, stood in the way and stopped progress. No one would listen to Lesseps. When at last people opened their ears to him, England took fright, and the scheme was vigorously opposed. Only one daily journal, the *Times*, gave him a lukewarm support. We took from the first a different view. Leaving politics on one side, we dealt with the engineering aspect of the scheme. The following extract from The Engineer, July 17th, 1857, serves to illustrate our attitude:—"Lord Palmerston last week did not hesitate to give a very decided opinion as to the Suez Canal question, and if an opinion of his lordship is sufficient to prevent the carrying out of this scheme, it is of course shelved for this century at all events. We are not disposed to quarrel with the Premier as to his views, politically speaking—they may be sound or not, and it is not our province to discuss them—but when he asserts that the construction is impracticable, we take leave to say he is wrong. The practicability of the construction of the Suez Canal has been attested by the first engineers of the age, whose opinions none can venture to controvert. This is all we can say at present, and all we have ever said, so far. We leave other considerations for those better able than ourselves to settle, though we may venture to suggest that what is sauce for the goose is usually considered ditto for her helpmate; and if there be any weight in the suggestion that our Indian Possessions might be readily opened to the encroachment of Russia or France by the Suez Canal, it undoubtedly would, at the present time, were it constructed, contribute very greatly to the relief of the public mind by facilitating the arrival of our troops in our disturbed Indian Empire."

Late in 1855 nothing had been done, and De Lesseps was already fifty years old; at last the Emperor Napoleon III. gave him an audience, others lent aid, and finally, in January, 1856, he got a concession from Said Pasha, and in 1859 the works were commenced. A canal, with sufficient water to admit of the passage of steamboats, was opened on August 15th, 1865. The channel was widened and deepened by special machinery, and in March, 1867, small ships were able to make use of the canal. The waters of the Mediterranean mingled with those of the Red Sea in the Bitter Lakes on August 15th, 1869, and the event was commemorated by grand *fêtes* at Suez. On the 20th of the following November the canal was formally opened at Port Said amid a series of brilliant festivities, as recorded in our pages at the time. As to what this highway of nations has become, an idea may be formed when we say that the Peninsular and Oriental Company have paid in one year £240,000. In the year 1891 the canal receipts reached £3,260,000. The toll on a large cargo steamer sailing from England to Bombay amounts to from two to three times the cost of all the coal she burns on the voyage.

As to the way in which the canal was constructed, the disputes concerning the Sweet Water Canal Company, the questions about the difference of levels between the Mediterranean and the Red Sea, Robert Stephenson's report, the Corvée, and a dozen other matters, the history has been fully written. At one period Ferdinand de Lesseps was the most abused man in Europe. But his success conquered all opposition. The canal became a fact; so did De Lesseps' reputation. Honours were showered thickly on him, and at one time it required some courage tosay that he was not an engineer.

During the remainder of his life Count de Lesseps had one dominant desire. He wanted to cut more canals. At all times he believed with straightforward innocence in himself. The success of the canal, the laudation of the nation, only strengthened him in the conviction that he could do what he pleased with the face of the earth. It is in no wise remarkable. The history of the Panama Canal has yet to be written. For ourselves, we have no hesitation in saying that Count de Lesseps was perfectly honest in all that he said and did concerning it. Nothing was done in the way of actual work until 1881, when the Count was seventy-six. At that age pardonable vanity is likely to flourish. If it was difficult for De Lesseps to doubt his own capacity at fifty, while the Suez Canal had yet to be created, it was impossible at seventy-five. A mistake was made by the French nation. There is no reason to believe that any large number of shares are held outside the shores of France. It would be waste of time to repeat the scandalous story of the Panama Canal. During the latter stages the old man was lying utterly broken down in mind and body in his château at La Chesnaye. It is pleasant to think that the veteran knew nought of the storm that raged around his name; and so at last Ferdinand de Lesseps died quietly, probably without the least idea that his end was near. Indeed, for a considerable period he has been more dead than alive—mentally at all events. As to his character, we do not think that can be much better expressed than it is in the following words written by the *Times'* own correspondent. After quoting a passage from an address by the late M. Renan, emphasising the individuality of the man, our contemporary goes on:—"Public opinion, which has alternately regarded him as an impostor or as a brilliant engineer, as a consummate financier or as a heartless swindler, will probably finally settle down to this appreciation of the originator of the Suez Canal. He was neither a financier nor an engineer, neither an impostor nor a swindler. He was a man of great originality, of indomitable perseverance, of boundless faith in himself, and of singular powers of fascination over others."

Death of a Well-known Mining Engineer.—A well-known figure in connection with mining engineering and the management of collieries in South Yorkshire in years past passed away on Saturday last at Silkstone Common, near Barnsley, in the person of Mr. James Wilson, for many years manager of the well-known Oaks Collieries, near Barnsley. Mr. Wilson claimed to be one of the first colliery managers or mining engineers who descended the shaft after the sad explosion in December, 1866, when 360 men and boys perished. Mr. Wilson was a native of Chester-le-Street, Durham.

## LORD SWANSEA.

The late Lord Swansea, who will probably be better known to fame as Hussey Vivian, was distinctly a conspicuous figure in the panorama of names and faces which has passed over a stage that represents three-quarters of the life of the closing century. Bessemer and Siemens were, in a sense, his contemporaries; Tyndal and Huxley were his social friends, and sometimes his friendly critics. Lord Swansea had not the gift, perhaps not the opportunity, of discovery as in the one case; and he certainly lacked the talent of literary expression with which Huxley and Tyndal have been enabled to make science seductive with a grace of style entirely new to our generation. There must be two orders of genius recognisable in the modern work-a-day world. There is the man who invents or discovers, and there is the man who discovers what the invention or discovery is worth. It will scarcely be claimed for Lord Swansea that he was a gratuitous propounder of fruitful ideas. Everyone would rather give him praise for his quickness of appreciation of the new ideas as they came to him, and the really splendid enterprise he showed in putting every suggestion offered him to the trial, and sometimes a costly trial, of practical experiment. The spirit of enterprise and the love of experiment would seem in Lord Swansea's case to have been faculties or inclinations of hereditary transmission. His grandfather was Mr. John Vivian, who was Deputy Warden of the Stannaries, and who founded a Cornish Metal Company ten years over a century ago. His father was a John Henry Vivian, who developed in an amazing manner the original Copper Works at Penclawdd, and was in after years—that means an early decade of our century—the creator of the great copper and spelter works at Havod, by which the name of the Vivians, under Hussey Vivian's intelligent and vigorous management, has been made known in the chief ports of the world. "There has never been a serious strike in our works in my lifetime," said Lord Swansea to the writer, and this was at a time when the persons employed at the furnaces and in collieries must have numbered four thousand. "How was that?" it was asked, in not unnatural astonishment. "Because I know every workman, and every workman knows that if it came to the push I could handle his tools. There's the root of common sympathy," said Lord Swansea—he was only Hussey Vivian then—"convince them that you can do their work, and can feel for their occasional hardships, and they are as nice a set of men all round as you could wish to meet at your dinner table."

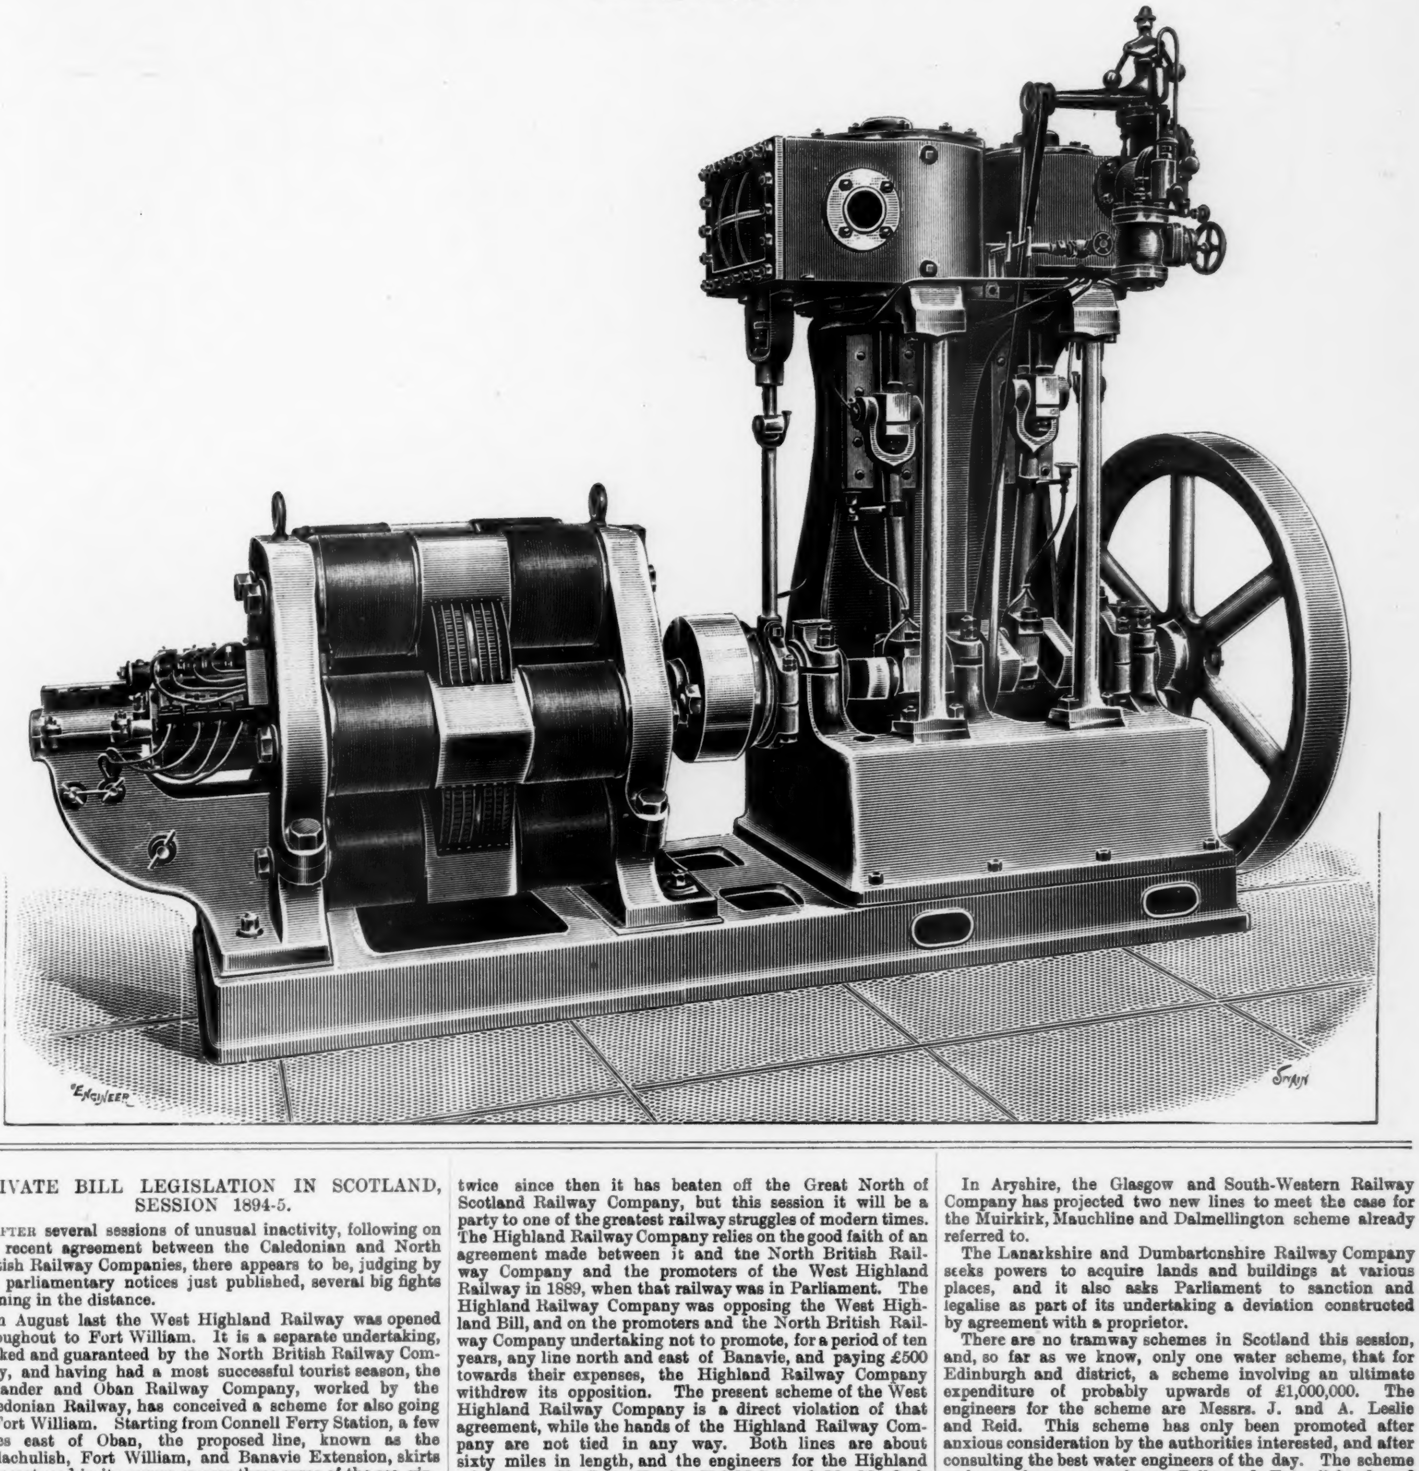
Lord Swansea could not have anticipated anybody, either in science or politics, and in both respects he must be regarded as a great assimilator rather than an originator. He had the keenest appreciation of the value of a new idea, and the conditions under which his early education had been gained will account at once for the comprehensiveness of his knowledge of his trade, and the keen apprehensiveness with which he welcomed—and adapted—other men's newer and more productive thoughts. Between Eton and Trinity College, Cambridge, he passed his elastic years, and employed his plastic mind in a "grand tour" of the technical colleges of the Continent. It may be said of him, to parody the epigram upon Whewell, that "metallurgy was his forte, and geology was his foible." He was from the beginning a metallurgist, and justified the traditions of his house. He became a chemist, because he needed knowledge of the solvents which would dissolve the ingredients of the rocks. But, however he gained his acquaintance with geology—or as he was wont to call it "lithological lore"—he most certainly must be said to have been a geologist so far advanced in his studies as to prove his equality to explorers of more conspicuous names, and to suggest that, if he told all he thought, the older geological school would have called him heterodox. It was his knowledge of chemistry which enabled him, at the Havod works, to capture and condense the sulphurous fumes belched out from the smelting fires. Sir Humphry Davy and Professor Faraday had been in consultation on the same subject in John Henry Vivian's time. It would seem that they tried every device, and succeeded in doing nothing to abate the nuisance. Then came out the Garsteinhoffer furnace. The Mr. Hussey Vivian of that day was quick to recognise its merits. The residuals, sulphates, and their cognates, proved to be more grist to the mill, and out of these experiments grew the one-time prosperous chemical works which Lord Swansea added to the rich estate his father left him.

But the deceased peer's geological knowledge became of greater public value at a date within the memory of most of our mining engineers. The great "Coal Scare" we are apt to associate with the names of Jukes, Hall, and Jevons. It will hardly be believed that there are public men who are still saying that our coal supplies will be exhausted in a couple of hundred years or so. Mr. Hussey Vivian, as he then was, knew more about our coal resources than the panic mongers. He moved for the Royal Commission, which in an unscientific way managed to arrive at something like a scientific conclusion. On this question of the coal supply Lord Swansea was always an optimist of the first water. There was, he said, at the time of the appointment of the Royal Commission, 24,000,000,000 tons of coal in the South Wales coal field unworked, but workable below the "imaginary and arbitrary limit" of a depth of 4000ft. Here was capital stock equal in value to £6,000,000,000, or about seven and a-half times the National Debt "cut off from the resources of South Wales alone by the assumed limit of 4000ft." And the optimism appears in a more pronounced manner when Lord Swansea wrote his notes of a tour through the United States in the year following the first Centennial Exhibition. It will be another tribute to his excellent memory to quote, for the benefit of those who have forgotten, the significant passages in which Mr. Hussey Vivian described the portentous dimensions of the North American coal fields. The coal area, he said, is enormous. It comprises 220,166 square miles, of which only 4800 are anthracite. There are, besides the true coal measures, 200,000 square miles of lignites, tertiary, and other inferior coals, but valuable fuel of their sort. "When we compare these stupendous areas with those of the United Kingdom, amounting to only 2920 square miles, and yet consider that our Commission arrived at the conclusion that we have more than 90,000,000,000 of tons yet unwrought, the probable amount of coal in America will appear too vast for the human mind to grasp—as impossible to realise as the distance of the nearest fixed star or the countless hosts of heaven." The shrewd observer in 1877, optimist as he was, saw some of the counterpoising conditions of the American coal trade. "The great disadvantage under which America most always labour as a coal-shipping country," he said, "is the distance of the coal fields from the seaboard;" and the laws which govern time and space leave that ultimate conclusion of Lord Swansea practically as true to-day as when he committed it to paper.

# ELECTRIC LIGHT ENGINE AND DYNAMO, STEAMSHIP CALEDONIA

MESSRS. TANGYES, BIRMINGHAM, AND SIEMENS BROS, LONDON, ENGINEERS

(*For description see page 523*)



## PRIVATE BILL LEGISLATION IN SCOTLAND, SESSION 1894-5.

After several sessions of unusual inactivity, following on the recent agreement between the Caledonian and North British Railway Companies, there appears to be, judging by the parliamentary notices just published, several big fights looming in the distance.

In August last the West Highland Railway was opened throughout to Fort William. It is a separate undertaking, worked and guaranteed by the North British Railway Company, and having had a most successful tourist season, the Callander and Oban Railway Company, worked by the Caledonian Railway, has conceived a scheme for also going to Fort William. Starting from Connell Ferry Station, a few miles east of Oban, the proposed line, known as the Ballachulish, Fort William, and Banavie Extension, skirts the coast, and in its course crosses three arms of the sea, viz., Loch Etive, Loch Creran, and Loch Leven. The bridges over these will be of some magnitude, but the name of the engineer, Mr. J. Wolfe Barry, C.B., is a guarantee that the line has been well laid out. As a matter of fact, the line was roughly surveyed in 1889, when the West Highland Railway Bill was in Parliament, and brought forward with the view of inducing the Committee to throw out the West Highland Bill. But the tactics were unsuccessful, as indeed was the Callander and Oban Company's Bill for a branch from Crianlarich down Glen Falloch to Loch Lomond, before the same Committee. Curiously enough, the Callander and Oban Company might have had this branch line, if it had been wise enough to support the Glen Falloch Railway scheme in the previous session. It remains to be seen whether the Callander and Oban Company will be more successful in the coming session. The Ballachulish, Fort William, and Banavie Extension is about forty miles in length, and the Bill asks for running powers over the Mallaig Extension of the West Highland Railway Company, in the event of that line being constructed by a Government grant.

From Fort William to Inverness two companies are contending for possession of the Great Glen through which the Caledonian Canal is formed. The Highland Railway Company, with its headquarters at Inverness, has projected a new line from Inverness down the north-west side of Loch Ness to Fort Augustus, thence to Spean Bridge and Fort William; while the West Highland Railway Company is projecting an extension of its line over very much the same ground. Hitherto the Highland Railway Company has been most successful in defending Inverness from every attack. In session 1883 it completely defeated the Glasgow and North-Western Bill to incorporate a new company, and twice since then it has beaten off the Great North of Scotland Railway Company, but this session it will be a party to one of the greatest railway struggles of modern times. The Highland Railway Company relies on the good faith of an agreement made between it and the North British Railway Company and the promoters of the West Highland Railway in 1889, when that railway was in Parliament. The Highland Railway Company was opposing the West Highland Bill, and on the promoters and the North British Railway Company undertaking not to promote, for a period of ten years, any line north and east of Banavie, and paying £500 towards their expenses, the Highland Railway Company withdrew its opposition. The present scheme of the West Highland Railway Company is a direct violation of that agreement, while the hands of the Highland Railway Company are not tied in any way. Both lines are about sixty miles in length, and the engineers for the Highland scheme are Sir John Fowler, K.C.M.G., and Mr. Murdoch Paterson, M. Inst. C.E., Inverness, while Messrs. Formans and McCall, of Glasgow, are the engineers for the West Highland scheme.

The Great North of Scotland Railway Company in its Bill does not contemplate the construction of any new works, but it seeks power to compel the Highland Railway Company to widen its line between Elgin and Inverness, and asks for running powers over that portion of the Highland Railway Company's system as well as over the branch line to the Caledonian Canal at Muirtown. As stated above, the Great North Company has been uniformly unsuccessful in its recent attempts to gain access to Inverness, the citadel of the Highland Railway Company. True, many years ago, before the existence of the Highland Railway Company, they had an Act for a railway to Inverness, but could not find the money to make it beyond Keith. Since then it has crept round to Elgin, but beyond Elgin it has never succeeded in getting the slightest foothold.

The Caledonian Railway Company is not directly in Parliament this session, but of course it is at the back of the Callander and Oban extension above described. And it is further interested in the Solway Junction Railway Bill seeking power to sell that undertaking to it. It still remains to be seen whether it is in any way identified with the invasion of the Glasgow and South-Western territory in Ayrshire by the Muirkirk, Mauchline and Dalmellington scheme.

The North British Railway Company seeks powers to widen the Helensburgh branch line, and to cut open the Dalreoch Tunnel on that line, improvements urgently required to accommodate the increasing traffic. It also seeks powers to make several new lines in connection with the Kirkcaldy and District Railway, and the East Fife Central Railway.

In Aryshire, the Glasgow and South-Western Railway Company has projected two new lines to meet the case for the Muirkirk, Mauchline and Dalmellington scheme already referred to.

The Lanarkshire and Dumbartonshire Railway Company seeks powers to acquire lands and buildings at various places, and it also asks Parliament to sanction and legalise as part of its undertaking a deviation constructed by agreement with a proprietor.

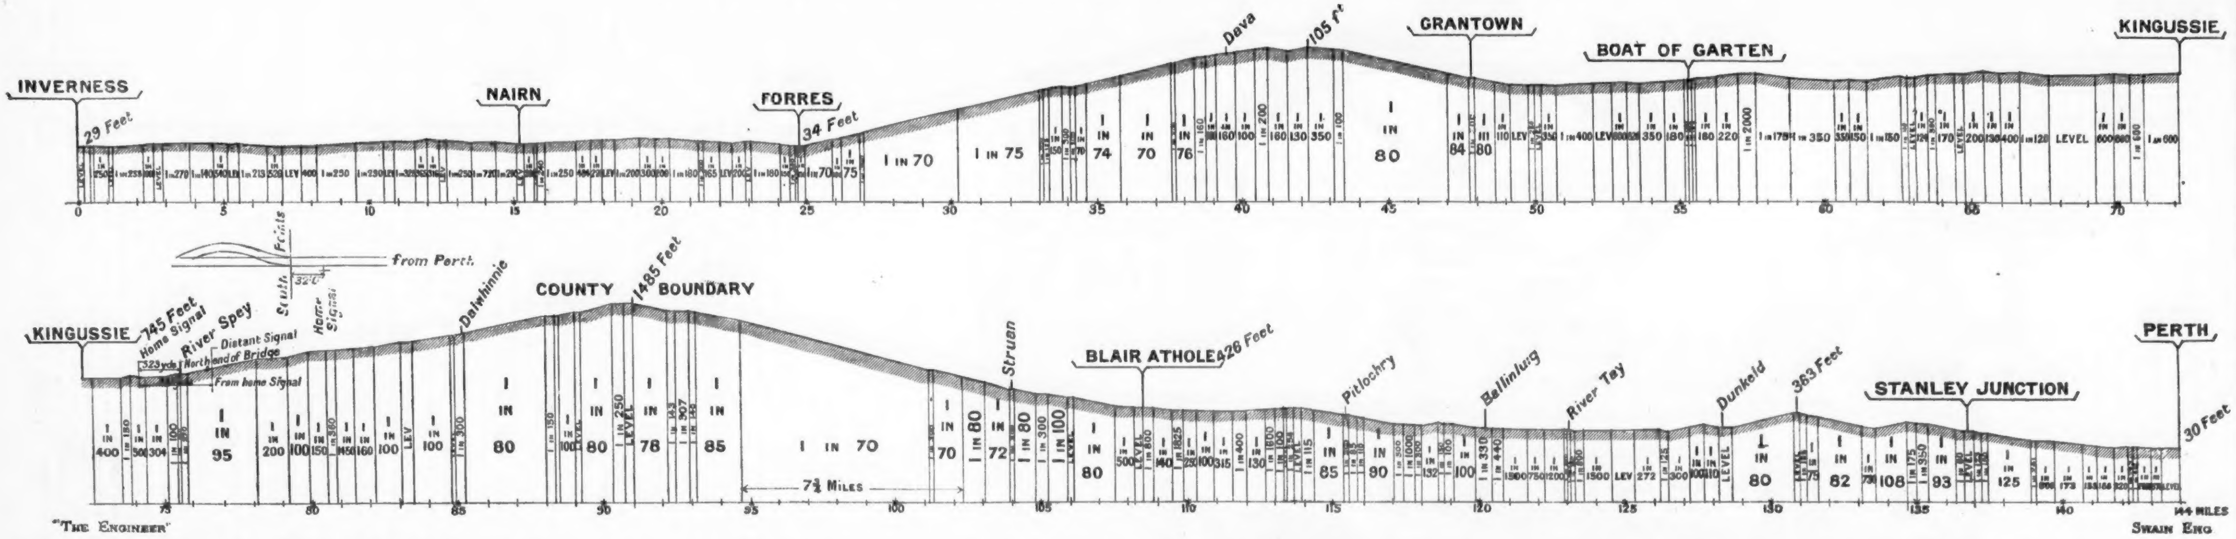
There are no tramway schemes in Scotland this session, and, so far as we know, only one water scheme, that for Edinburgh and district, a scheme involving an ultimate expenditure of probably upwards of £1,000,000. The engineers for the scheme are Messrs. J. and A. Leslie and Reid. This scheme has only been promoted after anxious consideration by the authorities interested, and after consulting the best water engineers of the day. The scheme embraces large reservoirs at Talla and Fairmilehead, and also some long aqueducts, besides railways for convenience in conveying men and materials.

The harbour and pier Bills are neither numerous nor important this session. Aberdeen seeks various powers, and Eyemouth proposes to construct several works for the greater convenience of the fishing industry, while Dunoon Burgh Pier may lead to a stiff fight between the Commissioners and the Hafton Trustees. Besides these, various powers are sought for Banff, Whitehills, and Blacksness.

Motherwell, a growing town closely identified with the coal, iron, and steel industries, seeks power to introduce the electric light, and notices have been given for Bills to introduce the electric light into Montrose and Brechin, evidently on behalf of the Scottish House-to-House Electricity Company, which recently started similar works at Coatbridge.

London Association of Foremen Engineers and Draughtsmen.—The usual monthly meeting of this Association was held in the K room of the Cannon-street Hotel on Saturday evening, the 1st inst., when the president, Mr. W. H. Bale, and the vice-president, Mr. R. J. Cook, were in the chairs. After the usual general business was over, which included the election of several new members, Mr. Cook gave an account of his recent visit to Newcastle, in connection with the annual dinner of the Newcastle Association. Mr. Cook stated that trade had been greatly interfered with by strikes, and at present some shops were busy, but most were quiet, a few very much so. He described the systems of working he saw in different shops, and gave a detailed description of the machinery in use in the North-Eastern Railway locomotive shops, where machinery seemed to be in use for everything it could be applied to, and organisation was such as to produce the best work at the lowest price. Some of the members made a few remarks on the report, and a vote of thanks having been passed to Mr. Cook, the meeting closed.

PROFILE OF THE HIGHLAND RAILWAY



# SIX COUPLED BOGIE GOODS ENGINE, HIGHLAND RAILWAY.

In 1888 we illustrated in our Christmas number Mr. Webb's compound locomotive, the Marchioness of Stafford. In 1890 we illustrated in the same way Mr. Worsdell's locomotive on the North-Eastern Railway. In December, 1892, we published drawings of Mr. Stirling's express engine on the Great Northern, all three remarkable locomotives. This year we publish drawings of what is, we believe, the most powerful locomotive in Great Britain—a goods engine, designed by Mr. David Jones, the locomotive superintendent of the Highland Railway, for working the heavy traffic, goods and passenger, on that exceptionally difficult road. Mr. Jones' engine has cylinders 20in. diameter, and 26in. stroke. This diameter of cylinder is not unknown in this country. It has been adopted for express engines by Mr. Dean on the Great Western, as will be seen from our impression for Nov. 2nd, 1894, where will be found illustrations of the latest types of express engines in use on that line. In 1867 Mr. Robert Burnett, when locomotive superintendent of the Metropolitan Railway, designed engines with 20in. inside cylinders, for working the St. John's Wood line, and six of these were constructed, and worked the traffic on that line for many years. These engines had, however, only 24in. stroke. These engines were six coupled, but in various ways they were less powerful than those of Mr. Jones. It is worth while to explain, however, why Mr. Burnett adopted these exceptional dimensions. In 1867 the Act of Parliament under which the St. John's Wood line was made provided for no physical junction with the Metropolitan Railway main line, the two companies being then distinct—although the Metropolitan entered into an agreement with the St. John's Wood Company to find rolling stock and work its traffic—and the St. John's Wood Company had obtained the authority of Parliament to extend its line from the Swiss Cottage Station to near the top of Hampstead Heath, by an incline of 1 in 27 in tunnel, with an intermediate station half way up the incline. As this section of the line would have had to be attacked *after* the engines had taken their loads up the steep incline from Baker-street to Swiss Cottage—a total rise of 94ft.—also in tunnel, where the engines had to "condense" most of the way, it was necessary to provide big cylinders to enable the engines to give out the required tractive force, with a boiler pressure diminished to 80 lb. or 90 lb. on arriving at the foot of the 1 in 27 incline. Now Mr. Jones' engines can, of course, keep the pressure all the way, and as they have 26in. stroke, we have no doubt that we are right in saying that they have the largest cylinder capacity ever found in a British locomotive. They have furthermore greater heating surface than other engines used in this country since the days of the Great Liverpool narrow gauge, and the Lord of the Isles class broad gauge engine.

It will be seen that in many respects the engine is a highly-improved American type. There are the outside cylinders and the bogie, and an enormous boiler. The driving and trailing wheels are provided with compensating levers. The driving wheels are without flanges, and the whole engine, notwithstanding its great length, is very flexible regarded as a vehicle.

Of recent years the traffic on the Highland Railway has been growing, and the company has been adding to its rolling stock. At the beginning of this year the directors decided on putting fifteen heavy locomotives on the road. These were designed by Mr. Jones, and constructed by Messrs. Sharp, Stewart and Co., of Glasgow. The traffic on the Highland Railway is very variable. At one season very heavy consignments of fish, which will stand no delay, have to be forwarded. At another agricultural produce, stones, and timber have to be dealt with. In the late autumn immense numbers of sheep have to be carried either to the southern markets or to lowland winter quarters. Then in summer there is exceptionally heavy tourist traffic to be dealt with. This stress of work has hitherto rendered the use of pilots necessary to an objectionable degree, and so Mr. Jones resolved that his new engines should be powerful enough to cope with any traffic almost, if not altogether, without help. The new engines accordingly keep time between Perth and Inverness with forty to forty-five loaded wagons, thus exceeding by more than a dozen wagons the power of the largest engines hitherto used on the line. A pilot is taken on only between Blair Athol and Dalnaspidal, where there is a long incline of 1 in 70, abounding in curves of only 20 or 22 chains radius to be faced. It must not be forgotten that the Highland Railway is a single line, and consequently the trains cannot be divided, for reasons which will be readily understood by our readers.

We have said that these engines are used to work heavy passenger trains, and their suitability for this has been proved by the fact that one of them has run down a five-mile bank with a mail train behind it in five minutes, or at the rate of sixty miles an hour, taking the curves of 30 chains radius with the utmost ease and smoothness.

The diagram which we give above is a profile of the road, and will give our readers a better idea of the difficulties of the traffic than a page of letterpress.

The contract for the construction of the fifteen engines was signed at the end of February, 1894. The first engine was delivered in September, and the remaining engines by the middle of November, and all the engines had run their 1000 miles guarantee by the end of the month.

Mr. Jones as designer, and Messrs. Sharp, Stewart, and Co. as builders, are to be congratulated on the success which they have obtained; and although it is as yet too soon to give figures, there can be no doubt that these powerful locomotives will effect a great saving in the cost of haulage.

Our supplements give an elevation and details of these fine engines. The principal dimensions will be found in the tracing. The louvres on the chimney are held to augment the draught.

By the courtesy of Mr. Jones, we are enabled to give a copy of the specification under which the engines were built.

### *Specification for Engine and Tender.*

The contract to comprise the making of fifteen locomotive engines and tenders. The same to be delivered free, and in complete working order, according to this specification, by the builders to the company, at Perth Station, not later than . . . . . . . . and prior to payment each engine and tender will be required to run 1000 miles; and the builders will be held responsible for all defects until they run that distance.

*Description.*—Outside cylinder six-wheeled coupled goods engine —four-wheeled circular and lateral bogie at leading end—and six-wheeled tender.

*Drawings.*—The locomotive engine and tender to be constructed to the design and dimensions shown on the accompanying drawings. Further drawings and particulars will be given if required.

*Materials.*—The quality of the materials used must be of the make specified, and when no such instructions are given, to be of the very best of their respective kinds. Boiler barrel, outside fire-box casing to be of mild steel. Longitudinal stays to be of mild steel. Copper for fire-box and fire-box stays to be of Bibby and Vivian's make. Tubes of boiler to be of copper, of Broughton and Everitt's make. All axles and tires to be crucible cast steel, of Vickers, Sons, and Co.—extra best. Springs to be manufactured by Thomas Turton and Sons, for engines, and Ibbotson Brothers, for tenders. Crucible cast steel castings to be ——. Bronze castings to be of J. Stone's make.

### DESCRIPTION OF ENGINE.

*Boiler.*—The barrel to be telescopic and formed of three plates, longitudinal joints butted and strapped, and placed above the water-line, transverse seams to be lapped, the whole of the boiler barrel and outside fire-box seams to be double-riveted, the tube plate ring that joins the boiler to tube plate to be bored and turned, all edges of plates to be planed, the dome with seat to be of mild steel or Yorkshire iron.

| | ft. | in. |
|---|---|---|
| Length | 13 | 9 |
| Diameter outside | 4 | $7\frac{7}{8}$ |
| Thickness of plates | 0 | $0\frac{9}{16}$ |
| ,, tube plates | 0 | $0\frac{5}{8}$ |
| Diameter of rivets | 0 | $0\frac{13}{16}$ |
| Pitch of rivets | 0 | $1\frac{7}{8}$ |

*Fire-box casing.*—Flush with boiler barrel, sides and crown to be one plate, to have eighteen longitudinal stays from back plate to front tube plate, stays to be screwed into the back plate, to have four T irons riveted to the crown part of casing, and to have on top a seat for safety valves, as shown.

| | ft. | in. |
|---|---|---|
| Length | 7 | 9 |
| Breadth | 4 | $10\frac{1}{2}$ |
| Thickness of front and back plates | 0 | $0\frac{5}{8}$ |
| Thickness of side and crown plate | 0 | $0\frac{9}{16}$ |

Bottom ring solid and slotted.

*Inside fire-box.*—To be of copper, seams to be riveted with iron rivets.

| | ft. | in. |
|---|---|---|
| Length inside at bottom | 7 | $0\frac{1}{2}$ |
| ,, ,, top | 6 | $10\frac{1}{2}$ |

### General Description.

*Mountings, &c.*—Boiler to be fitted with all gauge cocks, clack boxes, feed pipes, blower cock and pipe, whistle, washing out plugs, ash-pan with two air-tight dampers, as shown. A patent steam pressure gauge of approved kind. Boiler to be lagged with dry pine wood, and covered with clean sheet iron, No. 14 W.G., fastened with iron hoops in the usual way. Cylinders each to have one lubricator of approved design, two easing cocks, and one from steam chest worked from the foot-plate, and to have one vacuum sight-feed lubricator. Wheels all to be keyed on shafts with one steel key, after being forced on with a pressure not less than 10 tons per inch diameter, balance weights to be solid in coupled wheels, distance between backs of all tires 4ft. 5½in., flanges to be 1½in. high. Bolts and nuts must be of Whitworth's standard threads, every nut to be hexagonal, and those for same diameter of bolt to be exactly same size. All gland nuts to be case hardened. Nuts inside smoke-box to be of hard brass. All rivets visible in completed engine and tender to be countersunk. Brands of makers of axles, tires, and boiler plates must be left visible outside. Buffer beam, buffers, draw-hook, and life-guards, as per drawings. Engine buffers to be Platt and Turton's patent, with wrought iron cases and heads polished. All india-rubber springs to be of Spencer, Moulton and Co. Dome covers to be of charcoal iron or mild steel. Each engine will have a number plate of brass on each trailing splasher, also four sand boxes for dry sand, and to be worked from the foot-plate—steam sanding for leading boxes. House over foot-plate to be made according to drawing. The plates carefully hammered and riveted; to be provided with windows as shown. Manufacturers' name plate to be put on driving splasher. A gong on right side of tender. To have one set of fire-bars; one set of tools complete, including two 16-ton screw-jacks, traversing, with ratchets, stand to be of brass, the base of wrought iron; one set of fire-irons complete; also a full set of lamps. These engines and tenders to be fitted with automatic vacuum brake, arranged as shown in drawing.

*Painting of engines and tenders.*—To be of the colours used by this company. A sample board will be sent to show colours and lines. The boiler to receive two coats of boiled oil and red lead, previous to being lagged with wood; the wood outside and cleading inside to have one coat of lead colour. The cleading, house, splashers, frames, tender, and wheels to have two coats of lead colour, three coats of filling up paint, and to be well rubbed down; two coats of light green colour, one coat of coloured varnish, then finished with two coats of the very best body varnish. Chimney and smoke-box to have one coat asbestos black and one coat locomotive black.

### Description of Tender.

The tender to be complete in every respect. The tender tank to hold about 3000 gallons of water; this, with the under frame, to be made of mild steel plates. The whole to be mounted on six wheels, the wheel base being 13ft. Feed pipes to be of copper, with brass flanges. India-rubber pipes, with coupling nuts between engine and tender. Axle-boxes to be of the best toughened cast iron, and to have bronze bearings, to be fitted with wrought iron liner in crown of box to enable bearing bush to be taken out; also to have wrought iron case-hardened sliding cover on top.

*Tank.*—To be made of ¼in. plates, all rivet holes outside to be countersunk, and rivets flush with plates. Side plates to be without seam.

### General Stipulations.

The sole design of this specification and accompanying drawings being to explain as fully as possible to the contractors the locomotive engines and tenders required by this company, no advantage is to be taken of any error or omission in either, as full particulars will be given on application to the locomotive superintendent, who will have power of inspecting them personally or by deputy during their construction, and of rejecting either material or workmanship which he or his substitute may deem to be not in accordance with the proper fulfilment of this contract. No alterations to be made, unless instructed by letter from the locomotive superintendent. The contractors to pay all patent rights involved in this contract, and show satisfactory proof thereof to this company prior to the final settlement. Everything of its respective kind, both of engines and tenders, must be interchangeable. All the holes in the boiler and fire-box plates must be drilled. No drift or mandril allowed to draw holes straight or in line. The boiler to be tested by the contractors to a pressure of 200 lb. per square inch, with hot water, and to remain under that pressure for thirty minutes, and after to 175 lb. per square inch in steam. The boiler must be tight, and show no signs of weakness under these pressures, before being lagged; to be tested in the presence of the engineer or his substitute, and the safety valves to be ferruled to a working pressure of 175 lb. per square inch.

D. Jones,
Locomotive Engineer.
Inverness.

*The Highland Railway Company.—Six-wheels Coupled Bogie Goods Engine, No. 103 Class.*

## SOCIETY OF ENGINEERS.

At a meeting of the Society of Engineers, held at the Town Hall, Westminster, on Monday evening, December 3rd, 1894, Mr. George A. Goodwin, President, in the chair, a paper was read by Mr. H. B. Ransom on "The Principles and Practice of Hydro-Extraction."

The author commenced with a brief outline of the laws governing centrifugal force, and illustrated them in various ways. The applications to which hydro-extractors could be applied were also dealt with, and the reasons why some materials could be satisfactorily dealt with in that way and others could not, were referred to. After stating the ordinary centrifugal force formula, examples were given to illustrate the danger attending the use of centrifugal machines when driven by badly governed engines. From some experiments which the author had made, it appeared that in one instance a little grit getting into the joints of the governor so influenced the speed that the pressure on the walls of the basket of a centrifugal machine would have increased 56 per cent. if driven from such an engine. Although this was taken as an extreme case, it was stated that very great increase in speed, and consequent risk, was frequently incurred owing to ill-governed engines and improper attention. Some figures were next given to illustrate the advantages and disadvantages of a safe system of constructing centrifugal baskets. The factor of safety of a plate basket was found to be only 3, as compared with the factor of safety of a steel wire basket of nearly 13. Although these figures are clearly largely the result of calculation, the discrepancy between them is obviously so great that the broad truth in practice—that a wire basket is stronger than a plate basket—is almost undoubted Attention was drawn to the fact that whereas marine boilers are subjected to smaller stress than is common in centrifugal baskets, the latter are not submitted in any way to official inspection or regulation. The construction of direct driven centrifugals was also dealt with, and some very interesting figures given in relation to the inertia of the reciprocating portions of these engines. It appeared, for instance, that in a 12in. by 8in. engine, making 1200 revolutions per minute, the force necessary to start the piston at the beginning of a stroke would amount to nearly 3½ tons.

The paper was accompanied by several tables and diagrams.

English Engines for the United States.—Messrs. Galloways Limited are now making for the Johnson Company, Ohio, U.S.A., two large pairs of horizontal high-pressure non-condensing engines. The larger engine has cylinders 55in. bore by 5ft. stroke, with crank shaft bearings 22½in. diameter, and the total weight of this engine will be about 300 tons. The smaller engine has cylinders 48in. bore by 4ft. 2in. stroke, with bearings 19½in. diameter, and the total weight will be about 200 tons. The pressure at which both will work is 150 lb. per square inch, and it will be seen that the engines are probably as large as any that have ever been made in connection with rolling plant.

The Institution of Junior Engineers.—The members have recently had the opportunity of visiting the *Globe* printing office, and Linotype machine installation. Under special arrangements made by the manager, Mr. W. T. Madge, they were each enabled to make a close and thorough inspection of the Linotypes, of which there are eight in operation. In the machine-room two Victory machines were seen running, and another printing machine of the same make, but much larger and of the latest type, was shown which had just been erected. The stereotyping department, contents-bill machine, and other features of engineering interest were seen. The chairman of the institution, Mr. H. J. Young, conveyed the members' thanks for the facilities extended to them in connection with the visit. At the meeting held on Dec. 7th, at the Westminster Palace Hotel, Mr. H. J. Young in the chair, a paper on "Waterworks and their Appliances" was read by Mr. William Mallock. There was a large attendance of the members. Dealing first with source of supply, the author described generally the formation of the soil over or through which the rain passed on its way to the two classes of source—above-ground and underground; and reference was made to the systems adopted by the larger cities throughout the kingdom for obtaining their supplies. Diagrams were exhibited showing the arrangements and appliances in connection with London waterworks for well-sinking, boring, and driving headings into the chalk to the underground sources. The supply derived from London wells was gradually being exhausted, as was proved by their fall of water level to the extent of 10in. average per year; the above-ground source of supply would, however, be sufficient for many years to come. The geological formation of the Thames watershed, comprising an area of 3500 square miles, was described, from which it was noticed how that on account of the extensive natural filtration it undergoes before passing to the river, the Thames water was so much purer than the river waters of the north country, where the soil was generally impervious, and therefore unfit for filtering processes. In considering the question of storage, to which great importance was attached, various schemes were investigated applying to London, including Hunter and Fraser's, which had been accepted by the Royal Commission; and a proposal of the author's, whereby pumping expenses would be avoided, and other advantages obtained. A detailed account followed of the latest practice in regard to the different appliances in connection with the process through which the water passed from the intake, through screens, subsiding reservoirs, filters, pumps, service reservoirs, valves, and mains to the consumer. The paper concluded with some remarks on waste prevention, which could best be secured by the adoption of Deacon's meters. They were being largely used by the more advanced water companies, and resulted in a great saving, in many cases of as much as over 50 per cent. In the discussion which followed, Messrs. R. W. Newman, Walter Hunter, F. L'Estrange, F. Fisher, B.Sc., W. Powrie, S. Boulding, and others took part.

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

100-*ton shear legs.*—At the Philadelphia navy yard shear legs of 100 tons hoisting capacity are to be erected. The front legs will be 26ft. 9in. apart at the base, and the bottom of the back leg will be 39ft. 4in., and 93ft. 10in. from the front legs in its forward and back positions respectively. The three legs will be connected at the top by a pin, from which the hoisting falls and blocks will be suspended. The back leg will be 134ft. 6in. long, and the front legs 114ft. 6in. The latter will be composed of eight angle irons 6in. by 4in., and four 4in. by 4in., riveted together and connected by lattice angles to form a column 4ft. square. The back leg will be built up of twelve angle irons 6in. by 6in., riveted by ⅞in. rivets in the same arrangement as the front legs, and connected by lattice angles 5in. by 3½in. to form a column 4ft. square. The pin connecting the heads of the three legs will be 16in. diameter and 8ft. 4in. long, carrying two cast iron sheaves, the pin holes of which are bushed with bronze ½in. thick. For the hoisting mechanism there are twelve sheaves and two idlers 42in. diameter. The foot of the back leg rests on a crosshead which is moved to and fro by a screw gearing, the crosshead traversing between two upper rails of 20in. rolled beams and lower rails of 12in. rolled beams, the length of traverse being 60ft. The screw is 65ft. 3in. long, 11in. diameter over the thread, and 14in. over the thrust collars. The screw has a double thread of 4in. pitch. There will be two engines with cylinders 10in. by 10in. with a vertical boiler carrying 100 lb. pressure. The hoisting rope will be a wire cable 1¼in. diameter and 1800ft. long.

*Trench excavating machine.*—For excavating sewer trenches in city streets, where it is important to obstruct as little of the width of the street as possible, several forms of hoisting and conveying machines are used, some of which—consisting essentially of a fixed cable over the trench on which run carriers with buckets which are raised, lowered, and hauled by running cables—I have previously described. The Moore machine, which has been used in several cities, has a steel trestle or frame over the trench, a car with hoisting attachments running along the trestle and hoisting, lowering, and conveying the buckets. The trestle is 288ft. long, consisting of sixteen steel frames in the shape of the lower half of letter A, the feet having wheels which run on rails on each side of the trench, and the top horizontal portion carrying the track for the conveyor car. With ten bottom-dumping buckets of 30⅓ cubic feet capacity the machine will excavate 800 cubic yards per day. The width over base of frames is 14ft. The conveyor car has double-flanged wheels, has a hoisting plant controlled by men on the car, and is run in and out along the trestle by a wire cable. A brake is used to hold it in any position on a grade. The buckets are of steel, with hinged bottoms. At the rear end of the trestle is the engine-house, carried on wheels. The 25-horse power main engine has two cylinders 7in. by 10in., two drums 18in. by 27in., and is geared for high speed. All the levers are worked from an elevated platform from which the engine man has a full view of the trench. A vertical boiler 42in. by 93in. supplies steam. Boulders of three tons weight can be handled by chain slings. One bucket can be hoisted, conveyed, and returned in thirty seconds, the bucket raising earth from the excavation at the front end of the trestle and dumping it as back filling over the completed sewer at the back end. It can work to a depth of 35ft.

*Aluminium for boats.*—The Navy Department has just completed a test of aluminium as a material for ship boats, with the object of determining its adaptability to naval uses, with results that demolish some of the elaborate claims made for the new metal. On account of its comparatively light weight its utility on board ship would be almost inestimable, if it were not for the fact that it has been now shown to be exceedingly susceptible to the corrosive action of salt water. Two sheets, one-sixteenth of an inch thick, were immersed for three months at the Norfolk Navy Yard. One was stated to be pure metal, and the other slightly alloyed with nickel. The pure plate was thickly covered with large barnacles throughout its surface, and was more or less pitted by the action of salt water. The alloyed plate was encrusted with smaller barnacles and was badly corroded, being perforated and eaten away over much of its exposed surface. This plate was as injuriously affected as a combination of iron and copper would have been with the same exposure. In the opinion of naval experts it will not be advisable to build aluminium boats if they are intended to remain any length of time in the water, though its use may be advantageous on account of the great gain in lightness for metal work exposed to salt water only occasionally.

*Launch of the St. Louis.*—The steamer St. Louis, built for the transatlantic service of the American line, was launched at Philadelphia November 12th, a number of distinguished persons and a great crowd being present, including a delegation of representative men from the city of St. Louis. The ceremony of christening was performed by Mrs. Cleveland, wife of the President of the United States. The sister ship St. Paul is on the stocks, and both vessels may go into service next year. The stern tubes of the screw shafts run through what look like horizontal fins projecting on each side of the hull, the shafts thus being entirely enclosed, and shaft brackets being dispensed with. The leading dimensions are as follows:—Length over all, 554ft. 2in.; length between perpendiculars, 535ft. 8in.; extreme breadth, 63ft.; moulded breadth, 62ft. 9in.; moulded depth, 42ft.; depth from top of keel to top of first deck, 51ft.; designed load draught, 26ft.; number of decks, five, from 7ft. 2in. to 9ft. high each; 24 water-tight compartments; collision bulkhead, 33ft. from stem; gross tonnage, 10,770 tons; displacement at 26ft. draught, about 16,000 tons of salt water; cargo capacity on same draught, 1820 tons; but loaded to 28ft., cargo capacity is 3200 tons. The motive power will consist of two quadruple expansion, vertical, six-cylinder engines with four cranks, driving twin screws, and using steam at 200 lb. pressure. The estimated aggregate horse-power is 20,000. The first frames for the St. Louis and the sister ship St. Paul were laid on July 27th, 1893. Every item entering into their construction is of domestic material and manufacture, and they will be fitted throughout with every convenience and labour-saving device. Each of these ships will carry 320 first cabin and 220 second cabin passengers, 900 steerage, and 400 in the crew, including stewards, or 1840 persons in all. Economy in coal consumption is to be one of the features of these American ships.

*Shields for naval guns.*—Among the numerous investigations and experiments conducted by the Ordnance Bureau of the Navy Department, are tests of shield plates for deck guns which are otherwise practically unprotected. A report has recently been made on the latest experiments with specially-treated plates intended for shields for light calibre rapid-fire guns. The shields now in use in the navy on small guns are too thick and heavy, and naval officials are trying to find thinner and lighter plates of special manufacture which will give equal or increased resistance to penetration. The plates tested for this report had been previously tried at the Indian Head Proving Grounds; but having failed to come up to the requirements, they were sent to the Naval Gun Foundry and re-treated by a process calculated to give good results. There were four separate plates tried, all of which were of chrome steel. The first test was with a ½in. plate, manufactured by the Midvale Company. The gun used was a 1 lb. Hotchkiss, firing steel armour-piercing shells. The target was 113 yards away from the gun. Four rounds were discharged. In the first round the shell had a striking velocity of 1480 foot-seconds. It glanced on the plate and was broken up, making a gouge 1½in. wide, 3½in. long, and 1in. deep, and a through crack 4in. long. In the second round the striking velocity was 1609 foot-seconds. The shell was cracked, but did not break up. Excepting a slight gouge at the point of impact, the plate was not damaged. In the third round the striking velocity was 1750 foot-seconds. A piece of the plate was broken off, and two through cracks were developed. The fourth shell had the reduced striking velocity of 932 foot-seconds. Its point barely got through the plate. Two new through cracks were made in it. In earlier firing by the same gun previous to the re-treatment of the plate, the shells either went through the plate or penetrated to a much greater depth. The latter experiments showed, therefore, that the re-treatment produced higher resisting qualities, a fact which ordnance experts regard as encouraging. The second plate tested was ¼in. thick, and was also a product of the Midvale Company. It was attacked but once with one 1 lb. shell fired from a Hotchkiss gun. The shell went through the plate and was broken up by the impact. A small piece of the plate was dislodged, and a through crack 1½in. long was developed. Apparently no good results had followed the re-treating process. Subsequently the plate was fired at by the new model naval small arm. One bullet with a muzzle velocity of 2650 foot-seconds went through the target at a distance of 130 yards. A second ball with the same velocity nearly got through. Then followed tests of two plates manufactured by the Brooklyn Chrome Steel Works. The first plate tried had a thickness of half an inch, and the second a thickness of a quarter inch. The heavier plate was attacked by a 1-pounder Hotchkiss gun. The shell struck the target at an angle of forty degrees, with a velocity of 1256 foot-seconds. It broke off with an irregular fragment of the plate, and developed a through crack from the point of impact to the top, and from that point 4in. downward. The result of the shot was about the same as that which followed the earlier attack under similar conditions, except that the crack was less serious. The Brooklyn Company's ¼in. plate was fired at twice—first, by the 1-pounder Hotchkiss gun, afterwards by the ·236-calibre naval rifle. It had been badly cracked in the previous trials. In the first round the striking velocity was 578 foot-seconds. The shell glanced off the plate, gouging it to the depth of ¾in., and was broken up. Two through cracks, one 7in. long and another 2in. in length, were developed. The cracks were not as deep or as long as those made in the earlier trials, showing that the re-treatment had been beneficial. Four bullets from the navy musket were next fired, with a striking velocity of 1650 foot-seconds. Two balls, at a distance of fifty yards, perforated the plate, but at a range of 100 yards others splashed on the target, doing no damage. In the previous experiments all the ·236 bullets went through the plate. In relation to the experiments, it is stated that although the results were not as satisfactory as expected, it is believed that the navy will soon find thin gun shield plates that will make a better showing with respect to penetration than the heavier ones now in use. Only domestic plates are to be tested.

*Express locomotive for heavy work.*—The Boston and Albany Railroad has had built two powerful express engines to haul express trains of 200 to 250 tons over grades as steep as 1 in 66. The engines are of the eight-wheel type, having four coupled driving wheels, and a four-wheel leading truck or "bogie." The cab is of iron. The connecting and coupling rods are of I section. An extension smoke-box is used, with a short cylindrical smoke stack. The leading dimensions of these engines are as follows:—

| | |
|---|---|
| Cylinders | 19in. by 24in. |
| Diameter of driving wheels | 5ft. 1in. |
| Diameter of bogie wheels | 2ft. 9in. |
| Weight on driving wheels | 74,000 lb. |
| Weight on bogie wheels | 40,700 lb. |
| Total weight of engine | 114,700 lb. |
| Boiler, diameter at smaller end | 5ft. |
| Boiler pressure | 180 lb. per sq. in. |
| Fire-box size | 7ft. 6in. by 3ft. 4in. |
| Tubes, No. 13. B.W.G., number | 298 |
| Tubes, diameter | 2in. |
| Tubes, length | 11ft. |
| Grate area | 25½ sq. ft. |
| Heating surface, tubes | 1703 sq. ft. |
| Heating surface, fire-box | 141 sq. ft. |
| Heating surface, total | 1844 sq. ft. |
| Smoke stack, inside diameter | 14in. to 16in. at top |
| Height from rail to top of smoke stack | 14ft. 2in. |
| Driving and rigid wheel base | 8ft. 6in. |
| Total wheel base | 22ft. 11in. |
| Steam ports | 1¼in. by 18in. |
| Exhaust ports | 2¾in. by 18in. |
| Slide valve travel | 5½in. |
| Exhaust pipe, double, with nozzles | 3¼in. and 3⅜in. |
| Journals of driving axles | 8in. by 11in. |
| Journals of main crank-pin | 5½in. by 5½in. |
| Journals of coupling rod crank-pin | 4¼in. by 3½in. |
| Tender, eight wheels, diameter | 3ft. |
| Tender, wheel base | 14ft. 2in. |
| Tender, weight empty | 37,200 lb. |
| Tender, coal | 8 tons |
| Tender, water | 4000 gallons |
| Wheel base of engine and tender | 45ft. 11in. |
| Total length of engine and tender | 55ft. 7½in. |

The engine is fitted with the Martin steam heating fittings for the train, and with the Westinghouse brake on driving wheels, tender wheels, and for train.

*Storm window.*—There is frequent inconvenience in locomotive cabs, steamboat pilot houses, &c., from the obscuring of the glass by frost and snow on the outside, or steam on the inside, requiring the engineman or pilot to open the window in order to keep a lookout, which is very objectionable in severely cold and stormy weather. To obviate this, a window has been designed having two panes of glass about ⅝in. apart, the space between being filled with water which is heated to about 100 deg. by a tube around the edge through which steam is passed. The steam is not in contact with the water, and there is no pressure on the water. It has been found very useful on locomotives during the severe winters which are experienced in the Eastern States. The window is also adapted for lighthouse purposes.

*Forests and forestry.*—The recent annual report of the Chief of the Forestry Division shows that the seventeen forest reservations now aggregate 17½ million acres, and the four national parks 3⅓ million acres. The sale of ripe timber on the reservations and public timber lands is permitted under supervision. The exports of wood and wood products in 1893 amounted to 43 million dollars, and the imports to 2½ million dollars. The total annual consumption of timber of all kinds is about 22,000 million cubic feet, or 350 cubic feet per capita, and the inadequacy of the present forest area to meet growing demands is very evident. This bureau has for some years been urging the adoption of a rational forestry policy, providing for the protection of the timber resources, the regulation of cutting, and the provision for reforestation where required. Its investigations into the strength and qualities of timbers show conclusively that the strength of pine is not affected by the withdrawal of resin for commercial purposes.

*Snow plough for electric railways.*—City and country tramways in districts subjected to much snow during the winter usually have a number of snow ploughs for keeping the track clear, and on electric railways they are very successful. For keeping the snow from settling or drifting deep, or to clear the pavement after the plough has passed, street sweepers with revolving brooms about 7ft. long are run over the line; but where the snow is deep it has to be ploughed off. The Taunton plough is a four-wheeled car with the corners bevelled, and sliding windows fitted in the ends and bevelled parts, so as to afford a good view. In front projects the plough, about 3ft. high at the nose and 4ft. at the back, formed of steel plates carried to a point in front and flaring out, to clear the side of the body of the car. Back of the plough is an adjustable wing on each side of the car, so as to increase the width of space cleared. For single track the edge of the plough is in the middle, delivering snow on each side; but for double track the edge is over the inner rail, delivering all the snow on one side of the road. The plough is raised and lowered by a lever; and is fitted with a rail cleaner held up to its work by a spring, which will give if the cleaver strikes a switch or crossing. There is a plough at each end of the car, the two being balanced, and the rear plough being 8½in. above the rail. The car is carried on four 33in. wheels with flanges ⅞in. deep, and the wheel base is 6ft. 6in. An electric motor is carried on one or both axles, as desired. Boxes for sand or salt are in the car, with pipes leading down in front of each wheel.

*Express locomotive.*—The following are the leading dimensions of the latest express engines on the Pennsylvania Railroad, which engines are of the eight-wheel type—four-coupled driving wheels and a four-wheel leading truck or bogie—and have tenders carried on two four-wheel trucks or bogies:—

| | |
|---|---|
| Cylinders | 19 × 24in. |
| Driving wheels | 7ft. |
| Truck wheels | 3ft. |
| Tender wheels | 3ft. |
| Wheel-base of engine truck | 6ft. 7in. |
| „ driving wheels | 7ft. 9in. |
| „ engine | 19ft. 9½in. |
| „ tender trucks | 5ft. 7in. |
| „ tender | 16ft. 2in. |
| „ engine and tender | 49ft. 3¼in. |
| Centre of truck to centre of driving axle | 11ft. 9in. |
| Centre of coupled wheel to front tender wheel | 10ft. 4¾in. |
| Centre to centre of tender trucks | 5ft. |
| Length from nose of pilot—or cow-catcher—to back of automatic coupler on tender | 57ft. 6½in. |
| Weight on driving wheels | 86,900 lb. |
| Weight on truck wheels | 38,900 lb. |
| Weight, total, of engine | 125,800 lb. |
| Boiler, diameter | 4ft. 10¾in. |
| Size of fire-box | 119¾ × 40in. |
| Tubes (number, 258), outside diameter | 1⅞in. |
| Tubes, length between tube-plates | 11ft. 4in. |
| Length of smoke-box, including extended front | 5ft. 7¾in. |
| Height from rail to centre of cylinder | 3ft. 6in. |
| „ „ centre of boiler | 8ft. 4in. |
| „ „ top of smoke stack | 15ft. |
| Length from front of smoke-box to back of fire box | 27ft. 8¼in. |
| Length of pilot or cow-catcher | 4ft. 3in. |
| Height of ditto | 3ft. 4in. |
| Back of pilot to middle of cylinder | 5ft. 4in. |
| From centre of smoke stack to centre of bell | 2ft. 7¼in. |
| From centre of bell to centre of sand-box | 3ft. 0¼in. |
| From centre of sand-box to centre of dome | 4ft. 4¾in. |
| From centre of dome to centre of safety valve case | 5ft. 2in. |
| Centre of dome to back of fire-box | 13ft. 6¾in. |
| Draw-bar pins of engine and tender, apart | 2ft. 9in. |
| Tender, height of frame from rail | 3ft. 4in. |
| „ length over frame | 21ft. 8in. |
| „ length of tank | 19ft. |
| „ coal capacity | 7½ tons. |
| „ water capacity | 3000 gals. |
| „ weight, loaded | 70,000 lb. |
| „ height from rail to centre of coupler | 2ft. 11in. |

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

THE negotiations entered into this week for manufactured iron have been for limited quantities only. In very few cases is there any conspicuous activity, and the end of the year will close quietly with one or two exceptions. The sheet mills are tolerably well situated for orders, and in most instances operations are carried on the whole of the week. Values of galvanised sheets are slightly firmer at £9 10s. to £9 12s. 6d. for 24 w.g. f.o.b., Liverpool. Some firms possessing a good reputation will not, however, accept these rates, quoting 10s. to 20s. above them as their minimum. Sheets for galvanising and working-up purposes are nominal at £6 10s.; doubles and trebles, £7. Iron suitable for heavy engineering requirements is tolerably active. Marked bars are £7 10s.; second-branded sorts, £6 10s.; common bars, £5 7s. 6d.; hoops and thin strip, £6 7s. 6d.; stamping sheets, £8; best thin sheets, £10; and tank plates, £6 15s. to £7. Current sales of pig iron are restricted to small parcels for prompt delivery. Staffordshire all-mine hot blast is selling at 52s. 6d.; part-mines, 40s.; and cinder, 37s. 6d. Lincolnshire metal is quoted here, net, 40s. to 41s.; Derbyshire, 39s. to 40s.; and Northamptons, 38s. to 39s., less 2½; West Coast ordinary forge hematites, 54s., and foundry, 56s. 6d. to 57s. 6d., with best ditto, 60s.

The new works of Thomas Parker, Limited, electrical engineers, were opened at Wolverhampton on Monday, the machinery being set in motion by the Mayoress. The Mayor, Lieutenant C. T. Mander, is chairman of the board, and the position of managing director is occupied by Mr. Thomas Parker, late engineer and works manager to the Electric Construction Corporation, Bushbury and London—formerly Elwell Parker, Limited. Mr. Parker's name is well known in connection with the Liverpool Overhead Electric Railway, and other public undertakings. The erecting shop has four bays, each 150ft. in length, two being 42ft. 6in. in span, and two 32ft. 6in. There is also a foundry 40ft. by 120ft., and a pattern shop 80ft. by 40ft. The large shop is equipped with three overhead travelling cranes, and the foundry has a large cupola and a 10-ton crane. There is some splendid machinery for milling, planing, boring, &c. &c., of the most modern type, and from first-class firms, including Hulse and Co., Manchester; Kendall and Gent, Manchester; Muir and Co., Manchester; Tangyes Machine Tool Company, Birmingham; Campbell and Hunter, Leeds, and others. The current for driving the machinery and lighting the works is generated by a 100 kilowatt dynamo, actuated by a 250-horse power compound engine, by Bellis and Co., of Birmingham. One of the side-planing machines by Hulse and Co. has a 20ft. stroke. A two-spindle vertical milling machine, by Kendall and Gent, is ten-speeded, and mills over surfaces 5ft. by 10ft. by 3ft. high. The roofs are on the special timber principle of McTear and Co., Belfast. Much of the ironwork throughout is by Heenan and Froude, Manchester. The works were built from the designs of Mr. Archibald Brevitt by Mr. Henry Lovatt, both of Wolverhampton. All classes of electrical engineering work, both for power and lighting, will be turned out. Considerable orders are already in hand.

The new form of Siemens gas-fired furnace is coming increasingly into favour in this district. So pleased have the Staffordshire Steel and Ingot Iron Company been with its fuel saving capabilities and general efficiency, that they have laid down a second one for re-heating large steel ingots. It is also meeting with growing approval for iron manufacturing purposes, among the Midland mills and forges.

A correspondent of one of the Birmingham newspapers, dealing with the question of road engines for agricultural traffic *versus* light railways, states this week that in Herefordshire, with about 120,000 inhabitants, there are some 600 engines at work, and during the last year they have moved about 250,000 tons from three to thirty miles, mostly in loads of from ten to twenty tons. Owing to prohibitive bye-law restrictions the engines are, however, of very restricted use to farmers, although they are of much use to manufacturers.

Very few farmers can produce loads of ten tons or over. It is stated that what the farmers require are light and speedy engines that collect smaller loads from the farms, and which would find them in great abundance. The design of the present heavy road engine is, it is suggested, entirely the outcome of the regulations, while if the regulations were made for the assistance of steam traffic "we should soon have engines that would be formidable competitors with the railways, and would show that the proposed light railways would be a very expensive competitor."

In the Herefordshire district a light railway might be made for £2000 per mile, costing £24,000 or thereabouts, while the cost of one single mile of such a line would, it is urged, provide road engines and carriages to move the whole of the produce of the district, except what would be always moved by light horse traffic. Such views are confirmatory of the opinions expressed in a recent leader in THE ENGINEER on this subject.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—With the close of the year so near at hand, there is naturally a disinclination to enter into business operations beyond such as are requisite to cover immediate actual pressing requirements, and this, added to the previous exceptionally depressed condition of the iron market, gives a more than ever quiet tone to the trade generally. Both in raw and manufactured material the buying going on is just now of the most limited weight, and there is a good deal of under-quoting to effect sales; in fact, at what may be termed makers' quotations, very little business is practicable, but in the present condition of the market perhaps no great importance can be attached to the excessively low prices which, in some instances, are being taken to secure business. The outlook of the future, however, does not in any way improve, and there is a continued more or less despondent tone as to the prospects for the ensuing year.

There was again only an extremely flat market on the Manchester Iron Exchange on Tuesday, business for the most part coming forward only in the most limited quantities. Pig iron still meets with only a slow hand-to-mouth sort of demand, with rather a weakening tendency in prices, transactions of any moment that do come upon the market being competed for at under makers' quotations. With regard to Lancashire pig iron, the position remains much as reported recently; local makers still quote nominally on the basis of about 39s. for forge, up to 42s. for foundry, less 2½, at the works, but they have no chance of competing with Lincolnshire brands at these figures, and the only business local makers are doing is confined to occasional sales of foundry to regular customers, where they are favourably situated with regard to the rates of carriage. Some extremely low figures have been quoted during the week for Lincolnshire pig iron, prices for which are lower, out of all proportion as compared with other brands offering here. Forge qualities could be readily bought at about 37s., net cash, delivered Manchester, although makers do not actually quote under 37s. 6d., with foundry qualities averaging about 38s. 6d. to 39s., and Derbyshire foundry still nominally quoted, according to brand, from about 42s. 6d. and 43s. up to 45s., net cash, delivered Manchester. In outside brands there is a good deal of underquoting to get hold of business, but the current market quotations remain steady at about late rates, Middlesbrough averaging 43s. 10d. to 44s. 4d., net cash, delivered Manchester, Eglinton about 46s. 6d., and Glengarnock about 47s. 6d., net prompt cash, delivered at the Lancashire ports.

A very depressed tone continues throughout the finished iron trade, forges for the most part being only very partially employed, and prices gradually settling down to what were previously the minimum quotations to effect special sales. Lancashire bars do not now average more than £5 5s., with North Staffordshire about £5 5s. to £5 7s. 6d.; Lancashire and Staffordshire sheets range from £6 17s. 6d. to £7 2s. 6d., and Lancashire hoops are quoted £5 15s. for random to £6 for special cut lengths, delivered Manchester or Liverpool.

Only a very quiet business is still reported throughout the steel trade, with no really quotable change in prices; ordinary foundry hematites nominally average about 52s., less 2½ per cent.; low-class steel billets, £3 17s. 6d. to £4, and better qualities, £4 7s. 6d. to £4 10s.; steel boiler plates, £6 2s. 6d. to £6 5s.; and ordinary steel bars, £6 to £6 2s. 6d. per ton, delivered in this district.

The reports I gather from representatives of the engineering trades throughout the district do not indicate any material change in the position generally, and the reports issued this month by the engineering trades union organisations also are to much the same effect. The Amalgamated Society of Engineers, however, are able to report a further decrease in the number of unemployed members on the books of the society both generally and in this immediate district. This has been going on for the last couple of months, and, as I previously intimated, it is regarded as an exceptionally satisfactory sign that at this season of the year there should be even a small decrease in the number of unemployed, when usually an increase is looked for. The returns of the society from the various branches throughout the organisation do not show more than about 9 per cent. now in receipt of out-of-work benefit, whilst the returns in this immediate district, which a month back were quite 10 per cent., are now barely over 9 per cent. The returns of the Steam Engine Makers' Society show no material change, the number of out-of-work members remaining practically the same as last month, there being still about 5¼ per cent. of the total membership in receipt of donation benefit. With regard to the condition of trade, the reports from the various districts show no appreciable improvement, except that in one or two of the shipbuilding centres there are better prospects, and in some quarters the belief is prevalent that there will be a return to activity in this branch of industry with the ensuing year. In most branches of heavy engineering a fair amount of work is reported, but amongst locomotive builders trade is extremely slack, whilst boilermakers continue but indifferently employed.

A week or so back I referred to some possible friction between the employers and the workmen in the engineering trades of this district on the question of overtime. A conference has since been held of representatives of the Amalgamated Society of Engineers, Steam Engine Makers' Society, Pattern Makers, Brass Finishers, and Metal Planers, United Machine Workers, Amalgamated Smiths and Strikers, and Amalgamated General Tool Makers and Machinists, in this immediate district, at which the whole matter was fully discussed. The men take it as a grievance that, whilst so large a number of their members are out of employment, some of the shops should be persistently working overtime, and it was decided to send out a circular to the employers in the Manchester district, requesting that they would give due thought to the unemployed by abolishing overtime on new work, and where the staff of workmen was insufficient to cope with the work in hand, to adopt night shifts and engage extra men, so as to distribute the wage list among a greater number of men than was the case where excessive overtime was resorted to. No definite reply has yet been received from the Employers' Association with regard to this circular, but I understand it is under consideration. It does not appear that the men working overtime have any fault to find with the arrangement.

Messrs. Richard Johnson, Clapham, and Morris, of Manchester, have just added to their already large business, as manufacturers of safety lamps, screens, &c., by the purchase from the Deflector Safety Lamp and Miners' Appliance Company, which has ceased the manufacture of lamps and colliery requisites, the whole of their stock of miners' safety lamps, glasses, gauzes, lamp cleaning machines, patterns, &c., and also the safety lamp patents belonging to the above company.

At the annual meeting of the Northern Society of Electrical Engineers, held on Monday in Manchester, Mr. Henry Edmunds was elected president for the ensuing year, in place of Dr. John Hopkinson, F.R.S., who has held the office during the past year, Messrs. G. E. Preece, and W. P. J. Fawcus vice-presidents; Mr. John Darney, hon. secretary, and Messrs, A. B. Blackburn, Thomas Browett, E. Claremont, S. V. Clirehugh, G. S. Corlett, E. W. Cowan, C. M. Dorman, G. W. Lowcock, E. Manville, J. H. Rider, J. Taylor, and C. H. Wordingham, members of the Council of the Society. At the same meeting Mr. Alfred H. Gibbings read a paper on the "Commercial Possibilities of Tramcar Traction considered as a Municipal Undertaking," in which he referred to the three forms of electric traction now in use, viz., the underground channel, or conduit system, overhead wires, or trolley system, and accumulators, and described in detail an accumulator system he had recommended for adoption by the Corporation of Hull. Dealing with the general question, he said he had, however, come to the conclusion that the secret of success lay not so much in the adoption of any particular method of electric traction, however superior it might be, as upon enlisting and utilising services to which other enterprises could be made to contribute. Separately they might be only just paying their way, but combined it might be possible to make an exceptional success of both, and he urged that in connection with the accumulator systems corporations who had erected destructors for dealing with their refuse might combine these very effectively and economically in generating the power for application to electric traction.

Throughout the coal trade extreme depression continues the general complaint, all descriptions of fuel meeting with only a very slow demand, and three to four days per week continues the average that pits are working. Considering the season of the year, the sale of house-fire qualities continues extremely moderate, and the reductions made last week by one of the leading firms in the Manchester district have been followed by similar concessions on the part of other colliery concerns in the immediate neighbourhood. Generally, however, in other districts quoted rates remain unchanged, but there is a good deal of irregularity as regards actual selling prices in the open market. Best house coals do not average more than 10s. 6d. to 11s., seconds qualities 9s. 6d. to 10s., with common house coals about 7s. up to 8s. per ton at the pit mouth.

There is also but a very poor demand for the lower descriptions of fuel suitable for iron-making, steam, and general manufacturing requirements, and with excessive supplies offering, prices are extremely low, scarcely averaging more than 6s. 6d. for steam and forge coals, at the pit mouth. With regard to engine classes of fuel, common slack ranges from 3s. 6d. to 4s., with better qualities about 4s. 6d. to 5s., 5s. 6d. per ton being got in special cases, at the pit mouth.

For shipment only a very limited weight of business is reported, and prices are rather lower, if anything, common steam coal being readily obtainable at about 8s., with better qualities 8s. 6d. per ton, delivered at the Garston Docks, or the High Level, Liverpool.

*Barrow.*—In the hematite pig iron trade business is still very quiet, and neither on home or foreign account is any life shown. Prices are easy at 43s. 4½d. net cash, sellers of warrant iron, and 43s. 3½d., buyers. Makers still quote 44s. to 45s. per ton for parcels of mixed Bessemer Nos., net f.o.b. Stocks of iron have been increased during the week to the extent of 1000 tons, and now stand at 170,632 tons, being an increase on the year of 76,000 tons. Another furnace has been blown out, and now there are only 31 in blast, compared with 33 in the corresponding week of last year.

Steel makers are short of orders well nigh all round. Rails are quiet, although prices are down at £3 10s. for heavy sections. No new transactions are noted in plates, but the mills are busy. Slabs, blooms and wire rods are quiet. Billets and hoops in slow request, tin bars in small inquiry. Heavy steel castings are wanted.

The shipbuilding and engineering trades are by far the most brisk industries in the district, although no new orders are reported, but the contracts already in hand are considerable, and are likely to maintain activity for a couple of years to come. During this year the Naval Construction and Armaments Company has built shipping representing 20,656 tons, and has constructed engines of 29,550 indicated horse-power. Last year this company built 19,552 tons of shipping, and engines of 30,800 indicated horse-power.

Iron ore is still very depressed, and even the local demand showed further shrinkage. Prices are easy at old rates, 8s. 6d. for ordinary, and 13s. 6d. per ton for the best sorts net at mines. Coal and coke are depressed, the demand is very quiet. Deliveries are plentiful. Prices are steady at late rates.

Shipments of pig iron during the past week from West Coast ports amounted to 6310 tons, and of steel 3893 tons, compared with 4000 tons of pig iron, and 6053 tons of steel in the corresponding week of last year, an increase of 2310 tons of pig iron, and a decrease of 2160 tons of steel. The aggregate shipments up to date this year are 333,055 tons of pig iron, and 367,660 tons of steel, compared with 262,842 tons of pig iron and 413,012 tons of steel in the corresponding period of last year, an increase in pig iron shipments of 70,213 tons, and a decrease of 75,352 tons of steel.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

The slight improvement noted in the house coal trade last week has had the effect of stiffening prices a little. It has not been materially felt at the collieries, some of which are still working on short time. Trade is pretty quiet, and should the present mild weather continue, it will not make much progress at present. The supply is still considerably above the demand in all sorts. Railway companies who have running powers to London, and are connected with local collieries, have materially advanced their tonnage during the week, but the metropolis is not taking the usual average at this period of the year. The only appreciable difference the Scotch strike seems to have had on the trade of this district is the fact that it maintained the business at a time when it was likely to be very dull, and caused a temporary stimulus. The men are complaining bitterly of their small earnings, and state that, even with the 30 per cent. on their wages, it makes little difference, as when they are in the colliery they are not fully engaged. The seaborne coal is in keen competition in the London market, and, owing to the more favourable terms on which it can be sold, prevents anything like better prices being obtained. Everything seems to point to a further decline in demand and a continued abundant supply.

Prices are about the same as when last reported. Silkstones are 9s. 6d. to 10s. 6d. per ton; Barnsley house, from 8s. 6d. to 9s.; Flockton is selling at the same rates; secondary qualities and thin seam coal are at present being mostly sold for locomotive purposes; the best qualities fetch from 7s. to 7s. 6d. per ton at the pits. Although steam fuel is not in very good request, a fair tonnage is being taken to Hull and the other Humber ports. Grimsby is also doing a moderate trade with South Yorkshire pits, notwithstanding the fact that Derbyshire colliery owners are energetic rivals for business with that port. Local proprietors have not much opportunity to compete for the Goole trade, owing to the improved railway facilities provided for West Riding manufacturers. When the Sheffield Canal is in working operation district pits will have a better chance. Steam coal ranges in price from 7s. 9d. to 8s. 3d., but Flockton, which is admirably suited for these purposes, can be had at 6s. 9d. to 7s. 3d. at the pits. There is certain to be a stiff struggle when railway companies commence the placing of their contracts. As yet there has been but little done in that direction. Gas coal, which is in increased request, is now being supplied at 7s. 3d. to 8s. per ton. Lower prices have prevailed lately owing to the large amount of fuel in the market. Small coal is in poor demand, fetching only about 1s. 9d. per ton. Manufacturing slack is plentiful at 3s. to 5s. per ton. Coke is fairly active, and Derbyshire, North Lincolnshire, and other parts are taking a good average tonnage.

In the heavy iron and steel branches there is generally little change to report. The season trade is now about over, and the operations for the year can scarcely be set down as satisfactory. One or two firms are exceedingly well off for work. That condition of things, however, is not of wide application. There is a disposition to regard the outlook as somewhat gloomy for the future. Other manufacturers look forward hopefully to better business during the New Year, and their view of affairs is strengthened by certain sure signs, such as the large withdrawal of money from the banks, to make preparations for an augmented volume of business in the beginning of 1895. Recent railway traffic returns have been so unsatisfactory, that many of the principal companies, although they are admittedly short of locomotives, wagons, carriages and stores, have not sufficient confidence in the immediate future to place their orders. One we hear of is the Midland Railway Company, which has recently given out some work in rolling stock, although not to any great extent. The North-Eastern Railway Company is also asking for tenders for a considerable quantity of stock. An improvement in railway traffics would at once favourably affect business in the Sheffield district, as the production of this class of material forms a very large part of the work done in the heavy trades.

The anticipations entertained a few months ago that the present year, in regard to railway traffics, would equal at least the returns for 1892, are not being justified. Less has come into the Sheffield district by rail, and a good deal less has also gone out. If the business done during the opening months of the year had been maintained, the condition of affairs would have left little to complain of. In the East End districts, the summer and autumn months have found sufficient employment for the workpeople, and it is now pretty certain that a good deal of distress will have to be provided for before the spring of 1895.

Iron quotations remain as last reported, East Coast hematites at 50s.; West Coast hematites, 52s.; Lincolnshire forge iron, 38s. per ton, all delivered in the district. Bessemer billets are still quoted at £5 7s. 6d. The Scotch business, which used to be important at this season, has fallen away very considerably. Manufacturers attribute the lessened demand from the North to the effects of the coal strike, which operated there, as it did here, preventing the manufacturers from taking orders, which went elsewhere, many of them abroad. It would be interesting to know, but the information, of course, can only be obtained by the firms giving it themselves, how much good British business was lost—practically given to the foreigner—through the great coal stoppages in England last season and in Scotland this year.

At the works of Messrs. William Jessop and Sons, Brightside, there is in operation a new type of Siemens-Martin furnace, which has several advantages. One of its main features is the saving of coal, which is considerable. Another is in respect of repairs to the brickwork, &c., which, as well as being greatly lessened, are, when necessary, easily made, owing to the improved construction of the furnace. It has now been working for a considerable time on high-class steels, and has proved very successful. It is the joint invention and patent of Mr. Sydney J. Robinson and Mr. S. Pope.

Cutlery manufacturers report that they have not done so well this season in winter goods, neither in the home nor the foreign markets. An exception is the United States, which is rapidly recovering from the evil effects of the protracted suspense before the tariff arrangements were completed. Special goods for the American market are being largely ordered, and some goods, which have not been sent to the States for years, are again being manufactured to the order of American storekeepers. The tendency of the tariff to increase the quantity of cheap goods is still apparent, but in nearly every class of table cutlery there is more doing for that country. The spring knife cutlers are very poorly employed. The Australian markets are looking up and the Canadian demand is also hopeful of important business in the spring. The South African trade is not quite so brisk as in the autumn. Makers of edge tools are still well off for work, and the joiners' tool manufacturers report very good business. Skate makers, in spite of the mild weather, are making extensive preparations for the winter pastime. That trade comes suddenly, "like a thief in the night," and skate makers must not observe too carefully the signs of the weather, but go on making their skates to be ready to take advantage of the nipping frost when it comes.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

In spite of the unsatisfactory local statistics that were issued last week the market for iron and steel has not become worse as expected, but is, on the contrary, showing some improvement, for imperial statistics—the Board of Trade export and the revenue returns—have had more influence. They are more encouraging on the whole, and indicate that the general trade of the country is becoming more satisfactory. On this account, not only consumers, but also speculators are more inclined to speculate, and a decidedly brisker business than for some time past has been done this week, and in some branches at higher prices than have recently been quoted. In other metals than iron and steel, prices have moved upwards this week, and this has favourably influenced the iron market. The advanced rates have chiefly been in plates and angles, and the commoner qualities of Cleveland pig iron. The last-named have of late been unduly depressed, because the output was so much in excess of the requirements, and Cleveland forge pigs became absolutely "a drug upon the market." They have therefore had to take such steps that their furnaces should produce less forge iron, which they could not readily sell, and more of the foundry qualities which were in demand; the consequence is that the quantity of forge iron offering has declined, and the price for it has stiffened. A fair business in Cleveland pig iron has been done this week, and traders are not disposed to take such a despondent view of the prospects as they have held for some time past. Pig ironmakers have this year done a larger business, especially in Cleveland ordinary pig iron, the consumption of which this year so far has been 1,260,776 tons, as compared with 1,230,401 tons in the first eleven months of last year. The total production of Cleveland pig iron this year has been 1,298,513 tons (18,052 tons more than in 1893), and of hematite, spiegel, and basic pig iron 1,405,142 tons (185,041 tons increase on last year). Thus for the first time in the history of the North of England pig iron trade has the production of ordinary Cleveland iron been surpassed by that of hematite and other kinds, and the excess of the latter over the former has been 106,629 tons, every month this year contributing to that excess. The total production of all kinds of pig iron in the North of England has this year so far reached 2,703,655 tons, the largest on record, and surpassing that of 1890—the next best year—by nearly 100,000 tons. Of the Cleveland ordinary pig iron it is worthy of note that two-thirds has been exported (802,751 tons), but of the hematite, &c., only an eleventh part has been exported, the other ten-elevenths being either consumed in the district or sent to Sheffield and a few other inland places. Only 127,524 tons of hematite pig iron has been exported this year, against 165,803 tons last year.

A fair business has this week been done in Cleveland pig iron, and the tone of the market may be described as cheerful. The quotation for prompt f.o.b. deliveries of No. 3 Cleveland g.m.b. pig iron has this week been firmly maintained at 35s. 6d. per ton, and nothing below that has been taken. For delivery over the first quarter of next year, 35s. 9d. is asked and paid. There has this week been more speculation in Cleveland warrants than for a long time past, and up to 35s. 7d. cash has been quoted, but Wednesday's price dropped to 35s. 6d. The stock of Cleveland pig iron held by Messrs. Connal and Co. on Wednesday night was 90,964 tons, or 249 tons decrease this month. No. 4 Cleveland foundry pig has been advanced to 34s. 9d., and grey forge to 33s. 9d. The hematite pig iron trade does not yet show any improvement, but if the improvement in the plate and angle trades continues, the demand for hematite pig iron must likewise increase. Sellers of mixed numbers are asking 42s. 6d. per ton for early f.o.b. deliveries, and will readily take that, as their stocks accumulate. In Connal's stores alone there has this year been an increase of 41,482 tons of hematite iron, raising the total quantity held in the stores to 76,210 tons, and in makers' hands also there must have been a heavy increase, but statistics in respect to these are not procurable. This is very unsatisfactory for producers of hematite pig iron, and accounts for their having reduced their prices 3s. 6d. per ton where makers of ordinary Cleveland pig iron have not found it necessary to reduce theirs more than 1s. Exports of pig iron this month from the Tees are very fair, there being a large increase to Scotland, which counterbalances the loss in the continental trade. Up to Wednesday night the quantity of pig iron shipped this month reached 25,732 tons, as compared with 29,881 tons last month, and 25,472 tons in the corresponding month last year to 12th.

Some improvement has been reported this week in the shipbuilding industry, the low prices which builders quote for new vessels, coupled with better prospects for shipping and higher freights, have tempted owners to give out orders more fully than for some time past, and builders have been buying materials freely during the last few days. They will thus enter upon the New Year with better prospects than they expected. This year, in the

North of England, in spite of the interruptions to operations caused by the moulders' strike, shipbuilders will have launched a heavier tonnage than in 1893, and during most of the year they have been fairly well occupied, their worst time being the present. The fourteen builders on the Wear this year have launched vessels aggregating 166,503 tons gross register, 43,968 tons in excess of the 1893 return. The Tees shipbuilders have launched vessels as under:—

| | Gross register. Tons. |
|---|---|
| *Middlesbrough.* | |
| Sir Raylton Dixon and Co. | 32,220 |
| W. Harkess and Sons | 1,470 |
| R. Craggs and Sons | 4,003 |
| *Stockton and Thornaby.* | |
| R. Ropner and Sons | 28,028 |
| Richardson, Duck, and Co. | 23,312 |
| Craig, Taylor, and Co. | 12,809 |
| | 101,842 |

Last year's launches on the Tees totalled 93,915 tons, but in 1890 were 127,739 tons.

In the engineering industries some slight improvement is noticeable, and the brightening up of the shipbuilding industry will add to it. Some of the marine engineers having found trade so very bad of late have gone in for other kinds of work—the building of engines for electric lighting and power, a trade which they believe has a good future before it. Several firms in this district are using electricity to drive their smaller machinery. Ironfounders are doing only a very moderate trade. The creditors of the Egglescliffe Ironworks Company, Egglescliffe Foundry, near Stockton, had a meeting on Tuesday, and had such a satisfactory report presented to them by the official accountant that it was decided that the reconstruction of the concern be proceeded with at once, and it was expected that the works will not have to cease running. They were one of the few which were kept in operation throughout the Durham strike.

The demand for manufactured iron and steel is somewhat more active, and shipbuilders have this week bought more freely than for a long time, while the number of inquiries has increased, one being for quotations for a large quantity of plates for vessels that are to be built at Hamburg. Some of the ship-plate makers have put up their prices 2s. 6d. per ton, and ask £4 15s., less 2½ per cent. f.o.t. Angles are also in better request, and while some producers will accept £4 10s., less 2½ per cent. f.o.t., for both iron and steel angles, others do not come below £4 12s. 6d., less 2½ per cent. Boiler-plates are £1 per ton dearer than ship-plates, and girder plates 5s. dearer. Heavy steel rails are at £3 12s. 6d. net at works, and demand is very quiet. There has been a slight movement upward in the shares of some of the iron and coal companies this week, and in connection with those of Sir W. G. Armstrong, Mitchell and Co., it has been remarkable, viz., £10 per share and the £100 shares are now at 191. At the annual meeting of the shareholders of Messrs. Dorman, Long and Co., Middlesbrough, the chairman was asked whether the stocks had been taken at cost or invoice prices, and replied that unfortunately the prices were so nearly alike that it was of little consequence which price was adopted. He said also that the firm found orders very scarce, and what orders were about were very keenly competed for. He asserted that they were in a position to make angles and joists as cheaply as any other works in the country. He mentioned that they had now a very efficient bridge-building plant. They did not go in for large bridges, but were endeavouring to persuade engineers to adopt their joists for short spans, and they were doing so in a manner that was very encouraging.

The arrangement devised some two years ago by Mr. Thomas Mudd, of Hartlepool, for preventing the destruction of the propeller shafts of steamers by galvanic action and corrosion appears to have proved very successful. The shafts of some of the vessels then fitted with the device have just been examined, and show no trace of galvanic action or corrosion. Some eighteen months ago the s.s. Guernsey had her tail-shaft fitted with the arrangement, and on the shaft being drawn while the vessel was in dry dock lately, and the preserver pulled loose from its attachment to the shaft, it was found that the shaft had been entirely preserved, and the rubber sleeve itself had taken no harm, and was capable of being cemented down again for a further period at sea. The examination of the shafts of other vessels fitted with the sleeve showed that the sleeve itself was in a flexible and good condition, and when turned back from its attachment to the shaft the shaft and the ends of the brass liners were found in the same condition as when they left the lathe when new.

At the meeting of the North of England Institute of Mining and Mechanical Engineers, at Newcastle on Saturday, the president—Mr. Thomas Douglas—delivered his inaugural address, in which he referred to the greater security of life in mines which had now been attained in this country, and he criticised the report of the Commission which had been inquiring into the question of the part which coal dust took in causing explosions in mines. He expressed a hope that the Home-office, with the means at its disposal, would take up the question of stamping with its authority such explosives as they found could with safety be used under varying, and—if possible—under any circumstances. In relation to the application of electricity to coal mines, the president expressed the belief that it would ultimately lead to the adoption of locomotive traction under ground.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THE Glasgow pig iron market has been somewhat firmer in the last few days, with a considerable business in Scotch warrants, the prices of which have been on the basis of 42s. 4½d. to 42s. 6d. cash. Business in Cleveland iron has been limited, and the prices are a shade easier. For hematite warrants the inquiry is comparatively inactive, with little alteration in values.

Since last report the output of pig iron has been increased by the addition of three furnaces at Glengarnock, these producing ordinary iron. There are now 45 furnaces making ordinary and 25 hematite pigs—total 70, against 15 at this time last year, when a large number of the furnaces were out temporarily in consequence of a strike of miners.

The inquiry for makers' pig iron is fair, special brands selling pretty well, although the prices are difficult to maintain, being in several instances this week quoted 6d. to 1s. per ton lower:—G.M.B., f.o.b. at Glasgow, No. 1. is quoted 44s. per ton; No. 3, 42s.; Monkland, No. 1, 45s.; No. 3, 42s.; Carnbroe, No. 1, 45s. 6d.; No. 3, 44s.; Clyde, No. 1, 50s.; No. 3, 47s.; Gartsherrie, No. 1, 51s. 6d.; No. 3, 47s. 6d.; Calder, No. 1, 51s. 6d.; No. 3, 48s.; Summerlee, No. 1, 52s. 6d.; No. 3, 47s. 6d.; Coltness, No. 1, 54s. 6d.; No. 3, 51s.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 47s. 6d.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Dalmellington at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 53s.; No. 3, 50s. 6d.

The shipments of pig iron from Scottish ports in the course of the week have been 6772 tons, compared with 4345 tons in the corresponding week of last year. Of the total there was despatched to South America 200 tons, India 222, Australia 480, France 80, Italy 1020, Belgium 33, Spain and Portugal 120, China and Japan 618, other countries 150; the quantity sent coastwise being 3834, against 2766 in the same week of 1893.

The market for finished iron is in an inactive state. Abroad the Scotch product does not meet with much demand. Freights from Germany to the East are so slow, comparatively speaking, that with the cheaper prices for iron also prevailing on the Continent there is little chance of placing any orders here at present for unbranded iron. For common bars the demand is quiet. The steel trade is in an unsatisfactory state, the result, it is believed, indirectly of over-production. An understanding has for some time existed among the Scotch steelmakers as to prices, and a strenuous effort has been made by their Association to maintain these, as the only chance of making the business yield any return. In one or two cases, however, firms have been compelled to withdraw from the Association, as they could not keep their works going otherwise than by taking orders at reduced rates. The firmer prices quoted for ship plates, however, in the North of England within the last few days, and the placing of considerable orders for shipbuilding steel in this district, is expected to produce a rather better feeling—especially as the approach of the new year can scarcely be without its influence.

The shipments of manufactured goods from Glasgow in the past week embraced sewing machines to the value of £7585, other machinery £5130, steel goods £1820, and miscellaneous iron articles £18,820.

The coal trade is dull, or rather supplies are so ample that the market is in an easy condition, with prices tending downwards. The shipments in the past week fell short of those for the week preceding by 11,700 tons. In some districts the colliers are but partially employed, and by this time the men must be convinced of the unwisdom of their leaders in recently attempting to get up a fresh agitation in favour of an advance of wages.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

Up to the time of my despatch there has been an absence of the rush for steam coal which takes place generally before Christmas time, and, while collieries have been working less busily, complaints are heard on 'Change, Cardiff, of a lessened buoyancy of tone. Midweek there was a little freer inquiry, and it is not at all unlikely that next week will be a busy one. Prices have varied to the extent of 3d. on best steam coal during the last week, but as a rule no quotation has been below 11s. The latest prices, Cardiff, were:—Best steam, 11s. to 11s. 3d.; seconds, 10s. 3d. to 10s. 9d.; best Monmouthshire, 10s. 3d. to 10s. 6d.; dry coal, 9s. 6d. to 9s. 9d.; best small, 5s. 6d. to 5s. 9d. House coal remains in a steady condition, and there are strong grounds for believing in an appreciable advance, both in demand and price. At present prices are as follows:—Best house coal, 10s. 6d. to 11s; No. 3 Rhondda, 10s.; brush, 8s. 3d. to 8s. 6d.; small 6s. 6d. to 6s. 9d.; No. 2 Rhondda, 8s. 6d. to 8s. 9d.; small, 4s. 6d. to 4s. 9d.; through, 6s. 3d. For some kinds prices have increased 3d. per ton during the week. There is not much doing in coke. Furnace coke is selling at 14s. to 14s. 1d.; foundry, 15s. to 16s., Cardiff.

Pitwood has been coming into Newport and Cardiff freely of late, consigned from Bordeaux, l'Orient, Uddevalla, Hennebont, and Youghall. Now that good supplies have been coming in, prices have begun to recede, and this week quotations were at 16s. to 16s. 6d. Patent fuel is only in moderate demand; prices from 10s. 6d. to 11s. according to brand. As regards quality, both Cardiff, Swansea, and Newport, Mon., are turning out some of the best. In iron ore, as the end of the year is approaching, consignments are lessening, and this week only a few cargoes have come in. Cardiff and Newport prices are:—Best Rubio, 11s. to 11s. 3d.; Tafna and Garucha, 10s. 9d.; Porman, 10s. 6d. Markets dull.

Compilers of statistics are getting ready for their annual survey, and this week I have been favoured with totals including those of November, so that a fair idea can now be gained of the work of the year. I find that the aggregate coal shipments from the ports of South Wales for November amounted to 1,462,408 tons, showing a falling off to the extent of 27,760 tons. During the year, so far, Cardiff has shipped to foreign destinations 11,998,591 tons; Newport, Monmouthshire, 3,423,948 tons; Swansea, 1,634,108 tons; Llanelly, 209,587 tons. In the same period of eleven months, Cardiff has shipped 30,231 tons of iron and steel, 92,888 tons of coke, and 265.604 tons of patent fuel; Newport, 23,854 tons iron and steel, 5180 tons coke, 41,330 tons of patent fuel; Swansea, 2544 tons of iron and steel, 3009 tons of coke, and 293,297 tons of patent fuel; Llanelly, 197 tons iron and steel, no coke, and no patent fuel. As compared with other ports, Cardiff, as coal shippers to foreign destinations, maintains its lead for November, having despatched 867,891 tons, while Newcastle, the next, figures with 386,903 tons, and Newport, I am glad to note, comes in a good third of all the ports of the kingdom, with 215,420 tons, thus beating Blyth, Sunderland, and Hull.

With reference to the statistics for tin-plate, November shows but indifferently, as regards Russia, Holland, and Germany, with November, 1893. In November, 1893, the value of plates sent to Russia amounted to £19,235; in November, 1894, £1227. In November, 1893, America, the largest customer, took plates of the value of £201,026; in November, 1894, £274,114. The total value of all tin-plate shipments during the past month was £392,893, as compared with £344,326 in November, 1893. Australia and the East Indies showed a marked increase.

Cardiff is steadily adding to its fleet of steamers. A fine one has just been launched at McMillan and Sons' Dumbarton, thoroughly Welsh in name—the Gorsedd. It was built for Hurley, Matthews and Co., of Cardiff, and breaks Cardiff record by having a dead weight tonnage of 5600 tons to 5700 tons, or nearly 1000 tons more than the largest steamer at present registered at Cardiff port. Length between perpendiculars, 350ft.; breadth, extreme, 45ft.; depth, moulded, 28ft. 10½in.; to be classed A1 at Lloyds' under special survey. The engines, by Dunsmuir and Jackson, Govan, Glasgow, are of the triple-expansion type, with cylinders 25in. by 40in. by 66in., and stroke of 45in., with two boilers each of 16ft. diameter by 10ft. 9in. length, with a working pressure of 170 lb. The Gorsedd is, I hear, to have six steam winches, steam windlass, steam steering gear, and all the advanced inventions and methods.

Coal contracts are now being placed and at fairly good prices. Some of the latest reported have been secured by Lewis's Merthyr Nangabon Company and the Dowlais Company for delivery during 1895 to the Compagnie Générale Transatlantique. Prices are stated to be by the first 10s. 3d. less 3d., and 2½ per cent. discount; by the second about 10s. f.o.b.

At Cardiff on Saturday the Adare Colliery was put up for sale, but the reserve price was not reached, and it was withdrawn for private arrangement if possible.

I am pleased to hear that work has been resumed at the Bwllfa Colliery, Ton Pentre, one of the Ocean Collieries' pits. The men, to the number of 300, began work on Monday—after being idle for five months. This case is another illustration of the mistakes colliers—unfortunately for themselves—and others make. The general manager of the Ocean Collieries is a gentleman of marked ability, and a wide reputation for thorough conscientious ruling between man and man. The offer made by him five months ago after careful consideration was refused. It has now been accepted; but the collier has suffered, and so have the company.

The iron and steel trades continue to flag, and at no works can one see anything but moderate activity. A quiet hand-to-mouth trade appears to be the general characteristic, and tin bars, pig iron, merchant bars, and small goods constitute the chief requirements. As for steel rails, an exceptionally sluggish condition prevails, and will, I suppose, until the turn of the year. There is no change in iron and steel quotations, which remain at the last figures. I have heard of heavy steel rails at £3 12s. 6d., a drop of 2s. 6d. since last quotation; but it is evident makers have literally "touched bottom," and any change must be upward. I have not a solitary cargo of rails to chronicle for the week as despatched, but a quantity of tin bar imported.

The shipments of tin-plates last week were numerous, amounting to 69,808 boxes. The quantity received from works totalled 66,731 boxes, so stocks are decreasing though slowly. Swansea stock at present consists of 250,285 boxes. The market is lethargic, and the opinion on 'Change, Swansea, is that it will remain so until the wage question, now under discussion, is settled. Loadings are due next week to America four vessels, one to Russia, one Genoa and Leghorn, one to Dantzic and Revel, and one for Lisbon.

Blaenavon and Dowlais have been importing foreign ore largely this week, preparing, I hope, for better times.

Mr. Galloway's experiments at Merthyr last week, in demonstrating to a large number of colliers that coal-dust played no unimportant part in colliery explosions, elicited this week a letter from the secretary of the Dowlais, Cyfarthfa, and Plymouth Joint Committee, expressing the satisfaction of the workmen with the experiments. The workmen are "now satisfied," they say, "that coal-dust is a dangerous factor in explosions from its inflammability."

The electric light in Cardiff is improving steadily, and I anticipate will soon be generally used. The illuminating power shows a stride.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THIS week again business has only been quiet in the iron and steel trades, and whatever push there has been for supplies has been confined to immediate requirements. Prices, as a rule, show a want of firmness, but that is only what might be looked for. Demand for all descriptions of iron has been very limited for months past, and there is an increase in stocks to be noticed, while the cheap offers from foreign houses continue.

The Silesian iron trade in some of its branches is showing a little more activity on account of some fair orders for malleable iron which have been secured lately, but to get these orders makers had to further reduce their quotations. Generally, however, very little life is stirring in the iron industry. The steel works are in a most unfavourable position, nor is it at all likely that there will be an improvement in activity for the next months.

There are no orders for railway and engineering requirements holding out, and those previously secured have already for the greater part been effected. Few transactions of importance are reported on the Austro-Hungarian iron market, demand having on the whole lessened since former weeks. The pig iron trade continues very languid, consumers being of opinion that the inland makers, in consideration of the ever increasing foreign competition, must, sooner or later, agree to almost any price. Buying is, therefore, limited to the utmost. In the malleable iron department, girders and other articles of structural iron are tolerably well inquired for, while bars and plates remain in poor request; the steel trade is also very quiet all though. Contrary to all expectations, French iron business has not improved upon the week.

There are decidedly more offers than inquiries for both raw and finished iron, and the tendency of prices has been a trifle more weak in some instances. On the whole, however, a fairly good employment is reported at the mills, the contracts secured, though of small weight, reaching in most instances up to the end of the year.

In Belgium pig iron is somewhat neglected, but shows nevertheless a pretty firm tendency. The different articles of manufactured iron are also but weakly called for, with the exception of heavy plates, for which a fair inquiry is reported. The rail works and machine factories are irregularly employed. The present low quotations appear to have induced the State Railways to come forward with their orders; one for 1375 load wagons was given out last week, and so the shops are likely to be pretty actively occupied in the immediate future. The Belgian Government is reported to have resolved the abolition of the import tariff on foreign pig iron. There are still no indications of an improvement in the iron trade of Rheinland-Westphalia, on the contrary, demand is poorer than has been reported for several weeks past: in most branches prices have decreased, and the tone of the iron market is altogether depressed. In the iron ore trade there is little or no movement of any importance; Siegerland ores meet with a tolerable inquiry. During the last week the following prices have been quoted: Spathosee iron ore, M. 7·10 to 7·50 p.t.; roasted ditto, M. 10 to 10·30, best sorts M. 11 p.t. net at mines. Nassau red iron ore, 50 per cent. contents, stands at M. 9 p.t. free Dillenburg. Except that a downward tendency has been noticeable here and there, Luxemburg-Lorraine minette remains in much the same condition as before. Present notations are: M. 3·20 to 3·40 p.t. for red minette, 40 per cent. contents and M. 2·50 to 2·70 p.t. for the minor qualities.

On the pig iron market demand has, in a few instances, been a trifle more lively, and prices are rather well maintained. In the Siegerland, spiegeleisen has been brisk of sale during the past weeks, the majority of inland consumers having already ordered their supplies for the first quarter in 1895. Basis prices for spiegeleisen is still M. 52 p.t. For Rhenish-Westphalian forge pig, No. 1, M. 46 to 57 p.t. is given; No. 3, M. 40 p.t.; Siegerland good forge quality costs M. 44 p.t.; hematite, M. 63; foundry pig, No. 1, is paid with M. 63 p.t.; No. 3, M. 54 p.t. Basic only fetches M. 45 p.t.; Bessemer, M. 50 to 51 p.t. Iron for making steel continues to be offered at M. 45 to 47 p.t., according to quality. The situation of the malleable iron industry is still unfavourable, and prices are disappointingly low.

Inland as well as foreign demand for bars has decreased rather than improved upon the week. Most of the mills are fortunately pretty well supplied with orders for the next months, but a continued downward inclination is to be noticed with regard to prices. Structural iron, especially girders, is in moderate call; the hoop mills remain generally in very limited occupation, which may account for the willingness on the part of buyers to agree to reductions where orders for immediate delivery are concerned. In the plate and sheet trade a slow inquiry is reported; unremunerative prices and weak employment remaining the general complaint.

The appearance of both the wire and the rivet business continues very unfavourable, and the occupation of the machine and construction shops is anything but good. At the wagon shops there is also but a very moderate activity to be perceived; the order for 800 goods wagons recently given out did not cause any perceptible improvement in the general employment, as the contract had to be divided among the shops, and so each got a few wagons only.

Latest list quotations, per ton at works, are as under:—Good merchant bars, M. 100 to 105; rivet iron, M. 125; angles, M. 110 to 115; girders, M. 85 to 90; hoops, M. 105 to 110; billets in basic and Bessemer, M. 73 to 77; heavy plates, for boiler-making purposes, M. 140 to 145; tank do., M. 130 to 135; steel plates, M. 120 to 125; tank do., M. 110 to 115; sheets, M. 140; Siegen thin sheets, M. 120 to 125; in steel M. 110. Iron wire rods, common quality, M. 92 to 95; wire nails, M. 113 to 115; rivets, M. 145 to 150; steel rails, M. 112 to 115; steel sleepers, M. 106; fish-plates, M. 110 to 120; complete sets of wheels and axles; M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230.

ROYAL INSTITUTION.—The Christmas course of lectures at the Royal Institution, adapted to children, will be delivered by Professor F. A. Fleming, F.R.S., Professor of Electrical Engineering in University College, London. The subject will be "The Work of an Electric Current," and the first lecture will be delivered on Thursday, December 27th, at three p.m.

NAVAL ENGINEER APPOINTMENTS.—The following appointments have been made at the Admiralty:—Fleet Engineers, W. H. Gulliver to the Nile, and Thomas Burnes to the Hotspur. Chief Engineers, John J. Carey to the Amphion, and George Ramsay to the Blanche. Engineer, W. Gaisford to the Wild Swan. Assistant Engineers, new entries—George H. Elgar and Henry O. Andrews, to the Pembroke; George R. Byles and Hugh L. M. Ford, to the Victory; Arthur L. Butt and David H. W. Bain, to the Vivid; Harry Lashmore, to the Brisk; George G. Sisley, to the Brisk, temporarily; and Ernest L. Sagar, to the Jason.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, December 6th.

The meeting of Congress is watched with special interest by financial and manufacturing interests. Manufacturers are anxious to know if "pop-gun" tariff bills are to be passed, and the banking interests are anxious to know what sort of tinkering is to be done with finances. Public sentiment demands that both subjects be let alone. The iron trade is quiet. Small orders are coming in at all iron centres. Prices are steady, excepting in steel rails, which dropped to 22 dols., and will be driven to 20 dols., which ought to be the price, with billets at 15 dols.

Railway requirements are increasing. Large lots of old iron rails are being offered in western markets, and southern pig iron makers are endeavouring to place iron for delivery during the first four months of next year in western markets at present quotations.

## LAUNCHES AND TRIAL TRIPS.

Messrs. Wm. Simons and Co., Renfrew, have received from the Agent-General for Natal an order for a powerful suction pump dredger, which when completed will carry at least 1200 tons of its own dredgings. It will be fitted with two powerful sand suction pumps capable of raising about 4000 tons of sand per hour. This dredger will be employed in connection with the deepening operations on the Natal harbour bar.

On Wednesday, December 6th, 1894, the s.s. Saxony, built to the order of Messrs. David Mac Iver, Sons and Co., of Liverpool and London, left the Cleveland Dockyard of Sir Raylton Dixon and Co., Middlesbrough, for her official trial trip. She is a fine lined vessel of the partial awning deck type, with a long raised quarter-deck and poop, and has been specially designed and fitted for the River Plate trade. Her principal dimensions are 305ft. by 41ft. 3in. by 20ft. 3in., with a large deadweight capacity on a very light draught. She is rigged as a fore-and-aft schooner, the topmasts being fitted with Sidgwick's patent hinge arrangement, so that they can be lowered quickly when passing under low bridges. The engines have been fitted by Messrs. Blair and Co., Limited, Stockton-on-Tees, and are of the triple expansion type, having cylinders 23in., 37in., and 61in. by 42in. stroke, with two extra large steel boilers, working at 160 lb. pressure. The vessel and machinery have been constructed under the personal supervision of Mr. Roscoe, of Liverpool, consulting engineer to the owners, and she will be commanded by Captain J. B. Gordon, who has been many years in their service. The trial trip passed off most satisfactorily.

Ships launched during 1894 by Sir Raylton Dixon and Co., Cleveland Dockyard, Middlesbrough:—

| | Name. | Material. | Steam or sail. | British or foreign. | Gross register tonnage. | Indicated horse-power. |
|---|---|---|---|---|---|---|
| 1 | Ceylon .. .. | steel | steam | British | 4094 | 3000 |
| 2 | Claverley . | „ | „ | „ | 2837 | 1150 |
| 3 | Bearn .. . | „ | „ | Foreign | 1235 | 650 |
| 4 | Leyden .. .. | „ | „ | „ | 3378 | 1800 |
| 5 | Marlstow .. | „ | „ | British | 2386 | 1150 |
| 6 | Cierbana .. | „ | „ | Foreign | 1230 | 550 |
| 7 | Leopoldville | „ | „ | British | 3400 | 1800 |
| 8 | Saxony .. .. | „ | „ | „ | 2430 | 1250 |
| 9 | Normandy .. | „ | „ | „ | 2430 | 1250 |
| 10 | Lombardy . | „ | „ | „ | 2430 | 1250 |
| 11 | Homer .. . | „ | „ | „ | 2710 | 1500 |
| 12 | Steinberger .. | „ | „ | Foreign | 3600 | 1750 |
| | | | | | 32,220 | 17,100 |

The work has been very considerably stopped by strikes during the summer and autumn or the output would have been much larger. In addition to building the above-named steamers, a large amount of repairing work has been done both in dry dock and on the hydraulic slipway in the yard of the firm, over 160 vessels having been repaired, some of which had received very serious damage. Some extensive alterations to steamers have also been effected.

The Yorkshire College Engineering Society.—At a recent meeting of the Yorkshire College Engineering Society, presided over by Mr. Ewing Matheson, M. Inst. C.E., a paper was read by Mr. W. D. Wansbrough, of Lincoln, upon the "Building of a Boiler." The lecturer confined his remarks to the locomotive type of boiler. In tracing the growth of boiler construction during the last half century, one is struck by the improvement in the character of the work; instead of boiler plates of small dimensions made of inferior material and having punched rivet holes, inaccurately spaced and brought into coincidence by the frequent use of the drift, we see now a splendid material, plates of the largest dimensions, rivet holes drilled in position, hydraulic riveting, double riveted longitudinal seams with inside and outside butt strips, planed or tooled plate edge, careful annealing, and many other improvements. We may consider therefore that our boilers of to-day are as carefully fitted together as the parts of a steam engine. After describing the building and machinery of a modern boiler factory, the lecturer exhibited several samples of steel plates, sections, through rivets, and test pieces. In describing the hydraulic flanging of plates, the lecturer showed, by means of a small model in lead, how the throat plate of a boiler may be made in pairs and afterwards cut. This, of course, enables the throat to be pressed out of the centre as a ring, the operation of the hydraulic press being much assisted by the symmetry of the plate thus treated. In the discussion which followed, Mr. Ewing Matheson described a punch of special design which punches a small centre out first and then clears the hole out to its full size by shearing a ring of metal out equal to one-twelfth of the rivet diameter, thus cutting away the damaged material. This punch is being used where previously punching was not allowed. Messrs. J. H. Wicksteed, Watson, Hewson, the chairman and others spoke in the debate. The usual votes of thanks brought the proceedings to a close.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*28th November*, 1894.

23,060. Production of Stereoscopic Photographs, T. Brown, Salisbury.
23 061. Utilising Waste-heat, C. J. Bagley, L. Roberts and The Moor Steel and Iron Company, Stockton-on-Tees.
23,062. Hosiery Fabrics, J. Potterton, Leicester.
23,063. Firegrates, E. Hallam, Derby.
23,064. Supplying Fog Signals, W. Holmes and S. Jackson.
23,065. Manufacture of Tin Plates, A. J. Maskrey, Bristol.
23,066. Pipe Cover and Plug, W. Pearce, Birmingham.
23,067. Label-holder, W. Jones, Liverpool.
23,068. Printing of Photographs, H. W. Searle, Liverpool.
23,069. A Game of Defence Draughts, W. Wood, Manchester.
23,070. Boiler Furnaces, J. M. Robertson, Glasgow.
23,071. Construction of Wheels, S. T. Richardson, A. Smallwood and R. Price, Birmingham.
23,072. Locking Arrangements of Gates, W. T. Page, London.
23,073. Packing for Piston-rods, E. Samuel, London.
23 074. Tips for Boots, G. Mahaffy, London.
23 075. Flushing Water-closets, R. P. Stafford, London.
23,076. Automatic Catch for Doors, J. W. Harrison and J. Robinson, London.
23,077. Spinning Machines, R. Hassler, London.
23,078. Non-slipping Cover for Tires, A. Pellant, London.
23,079. Cloth Materials, J. G. Kinmond, Glasgow.
23 080. Wire-cloth, A. Cousland and Co. and G. H. May, Glasgow.
22,081. Tree Propagating, G. F. Griffin, Manchester.
23,082. Locks, J. M. Lockerbie and A. W. Wilkinson, Birmingham.
23,083. Extracting Shives from Casks, J. T. Thompson and A Slatter, London.
23,084. Producing Tinted Material, M. B. Church, London.
23,085. Brick Machine Table, A. Jolley and G. Hewett, London.
23 086 Electric Traction System, R. Kennedy, London.
23,087. Advertising on Cycles, S. T. Brown, London.
23,088. Suspensory Belts, W. P. Thompson.—(*W. J. Teufel, Germany.*)
23 089. Machines for Cutting Rubber, S. H. Foden, Liverpool.
22,090. Woven-wire Mattresses, T. Hilton, Manchester.
23,091. Washing Machine, W. Quait, London.
23,092. Casting Chains, W. H. Palmer and W. Gibson, London.
23,093. A New Toy, W. J. Lockwood, London.
23,094. Toy, G. Royle, London.
23,095. Radiators, C. F. Kite, London.
23,096. Reciprocating Cranks, J. Turnbull, Plumstead, Kent.
23,097. Cycle Driving Mechanism, F. W. Golby.—(*E Sauvain, France*)
23,098. Arc Lamp Feeding Mechanism, W. K. Partington, London.
23,099. Insulator to Prevent Humming, W. S. Cottis, London.
23,100. Speed Indicators, W. Milner and W. Wilson, London.
23,101. Insect Killing Composition, A. A Bécheraz, London.
23,102. Lamp Stoves, E. Rippingille and W. Porter, London.
23,103 Lotion, E. Horton, Bristol.
23,104. Roundabouts, A. Goodwin, London.
23,105. Cycles, A. Trouvé, London.
23,106. Axle Boxes, I. A. Timmis, London.
23,107. Firegrates or Stoves, W. and J. S. Elliott, London.
23,108. Dress Fastening, M. Stirling, London.
23,109. Coin-freed Machines, W. Northorpe London.
23,110. Window Sashes, F. J. Commin, London.
23,111. Method of Carbon Printing, V. Blanchard, Cambridgeshire.
23,112. Return Tickets for Railways, M. Vezzosi, London.
23,113. Photographic Mounts, Strong and Co. and C. Welsh, London.
23,114. Toy, P. D. W. Greville, London.
23,115. Watch Pockets, G. Henley and J. Henley, London.
23,116. Chimney Cowl, E. Pearson, London.
23,117. Apparatus for obtaining Alloys, L. P. Hulin, London.
23,118. Decorating Ramie Plants, P. P. Faure, London.
23,119. Dyeing, J. Arnold, London.
23,120. Athletic Boots and Shoes, J. W. Ward, London.
23,121. Tiles for Covering Walls, H. H. Lake.—(*J. H. C. G. Brandes, Germany.*)
23,122. Envelopes, H. H. Lake.—(*J. D. Petersen, Germany.*)
23,123. Mixing Clays, W. P. Campbell-Everdon and E. Prime, London.
23,124. Spraying Apparatus, R. Wallwork and A. C. Wells, London.
23,125. Stopping Runaway Horses, N. Sotiropoulo, London.
23,126. Window-catch Fasteners, F. Constable and F. P. Naldrett, London.
23,127. A Golf Scorer, W. Potter, London.
23,128. Small-arms, W. G. Froome, London.
23,129. Road Locomotives, T. L. Aveling, London.
23,130. Linotype Machines, The Linotype Company, Ld, and E. Girod, London.

*29th November*, 1894.

23,131. Manufacture of Stair Rods, E. W. Dobbs, Wolverhampton.
23,132. Improved Tackle for Fishing, S. Allcock, Redditch.
23 133. Manufacture of Laced Boots, J. Sullivan, Cardiff.
23,134. Puzzles, W., W. J., and H. H. Middleton, Birmingham.
23,135 Disinfecting, &c., Fluid, C. T. Gardner, Brighton.
23,136. Date Indicator, J. A. J. Morton, Gloucestershire.
23,137. Rotary Printing Machines, R. Sanson, jun., Edinburgh.
23,138. Turning Leaves of Music, A. Bale, Merthyr Tydvil.
23,139. Curvilinear Instruments, C. H. White, jun, Birmingham.
23,140 Combination Cruet, S. Skerritt and C Barker, Sheffield.
23 141. Sounding Machines, H. L. Allen and H. Boyd, Govan, N.B.
23,142. Utilising Heat from Gas, T. Sykes, Huddersfield.
23,143. Drawing Beer from Barrels, T. Bell, Liverpool.
23,144. Driving Nap-raising Machines, W. Holland, Manchester.
23,145. Coal Wrapper, F. H. Hall, London.
23,146. Pneumatic Tires, T. W. J. Martin and E. F. Walker, Dublin.
23,147. Vessel for Preserves, &c., W. S. Bell and T. J. Honeybourne, London.
23,148. Gully-dish and Grate, F. Thackeray, Darwin, Lancs.
23,149. Cycles, P. Frodsham, Manchester.
23,150. Cuff-link Holding Appliances, C. Horner, Halifax.
23,151. Window Sashes, W. Taylor, Glasgow.
23,152. Pressure Gauges, H. Brier and The Scotch and Irish Oxygen Company, Glasgow.
23,153. Wire Mattress Machinery, W. Waterhouse and T. W. Blantern, Birmingham.
23,154. Wire Mattress Machinery, W. Waterhouse and T. W. Blantern, Birmingham.
23,155. Spoonless Pot for Mustard, H. W. Handcock, London.
23,156. Baking Bread and Biscuits, G. Lawson, jun., Glasgow.
23 157. Warp Let-off Motions for Looms, R. Wilby, Huddersfield.
23,158. Wire Brushes, E. L. Levetus, Birmingham.
23,159. Electric Brushes, &c, E. L. Levetus, Birmingham.
23,160. Primary Batteries, &c, E. L. Levetus, Birmingham.
23,161. Pumps, R. Richardson, Glasgow.
23,162. Roller Thrust Bearings, W. J. Fanning, Manchester.
23,163. Brush Fastener, A. Everett, Folkingham, Lincs.
23 164. Vehicle Couplings, G. L, Lavington and E. A. Wright, London.
23,165. Protector, I. Kaufmann, London.
23,166. Waiters' Trays and the like, C. E. Corbitt, London.
23,167. Clay Tobacco Pipes, C. J. Saunders, Birmingham.
23,168. Holders for Candles, W. H. Bulpitt, Birmingham.
23,169. Brake for Beaming Frames, E. Ratcliffe, London.
23 170. Projector and Catapultum, G. S. Sidey, London.
23 171. Safety Boiler Clip and Cover, E. J. Frost, London.
23,172. Treating Heated Metals, G. A. Dick, London.
23,173. Protectors for Trousers, W. F. Tuson, London.
23,174. Closing Canisters, Boxes, &c., T. A. Prince, London.
23,175 Mechanism of Reaping Machines, W. Johnson, London.
23,176. Tongs for Coals, &c., J. P. Funt, London.
23.177. Dynamos, A. G. New and A. J. Mayne, London.
23,178. Supporting Rail for Piano Actions, A. Lexow, London.
23 179. Rearing Infants, H. H. Lake.—(*A. Lion, France.*)
23,180. Lock for Window Sashes, R. W. Barker.—(*T. W. Meyer, United States.*)
23,181. Automatic Brick-cutting Tables, S. Jefferies, London.
23,182. Locks for Railway Carriage Doors, S. Hammond, London.
23,183. Obtaining Arithmetical Results, R. F. Stein, London.
23,184. Stand for Gas Cylinders, T. P. Watson and J. G. Castle, London.
23,185. Fog-signalling on Railways, I. A. McDonnell, London.
23,186. Roof-lamps, W. McLaren and H. E. Brown, London.
23,187. Perfecting Printing Presses, H. P. Feister, London.
23,188. Die and other Stamping, M. M. Dessau, London.
23,189. Medallions and Checks, M. M. Dessau, London.
23,190. Lift, A. Renner, London.
23,191. Heating Apparatus, J. Grummitt, London.
23,192. Bells, J. M. Rimington and T. Shepherd, London.
23 193. Cams of Knitting Machines, H. H. Donner, London.
23,194. Preservation of Alimentary Substances, J. Imray.—(*La Société Anonyme des Matieres Colorantes et produits Chimiques de St. Denis, France.*)
23,195. Tipping-trucks, A. Chambers.—(*A. L Chambers, South Africa*)
23,196. Truck Axles and Lubricators, A. Chambers.—(*A. L Chambers, South Africa*)
23,197. Frames of Velocipedes, O. Imray.—(*A. Chobert, Belgium.*)
23,198. Treatment of Metallic Alloys, L. P. Hulin, London.
23,199. Portable Tent, E. S Farrow and W. Cumming, London.
23,200. Impermeable Hats, F. J. Elliott.—(*Mathias and Co., France*)
23,201. Printing Presses, A. J. Boult.—(*A. Pabst, Germany.*)
23 202. Self-opening Doors, P. R. J. Willis.—(*M. C. Plummer, United States*)
23,203. Springs for Electrical Switches, W. T. Burbey, London.
23,204. Heel Tips for Boots and Shoes, J. E. Evans, London.
23,205. Automatic Photographic Apparatus, J. F. y Girbau, London.

*30th November*, 1894.

23,206. Combination Gearing, A. R. Albert, Manchester.
23,207. Scaffold Fastener, J. Dennis, Leicester.
23,208. Setting Lacing Hooks, M. H. Pearson and C. Bennion, Leicester.
23,209 Automatic Tilter, T. L. Jennings and H. H. Stabler, Leeds.
23,210. Scenting the Atmosphere, J. Wheeler, Ilfracombe.
23,211. Windows and Window Cases, W. Cruickshanks, Glasgow.
23,212. Manufacture of Wire and Rods, J. C. Bull, London.
23,213. Earthenware Ventilators, F. Smith, J. J. Green, and W. Oates, Halifax.
23,214. Spiral Pencil-holder, &c., J. Rigby, Manchester.
23,215. Lanterns, V. Groom, Birmingham.
23,216. Draw-rolls of Cotton Machinery, J. Leese, Manchester.
23,217. Hanging-up Pictures, &c, J. K. Comrie, Glasgow.
23,218. Hydrocarbon Motors, E. Wiseman and J. Holroyd, Manchester.
23,219. Fixing Electric Arc Lamps, G. M. Harriss, Bray.
23,220. Producing Animal Charcoal, J. A. Yeadon and W. Adgie, Leeds.
23,221. Tool for Making Pile Fabrics, J. Whitfield, Northumberland.
23,222. Wringing Machines, J. Pain, London.
23,223. New Advertising Medium, P. Watson, Bradford.
23,224. Velocipede Crank or Pedal, W. Evans, Manchester.
23,225. Rubber Shield or Casing, W. Moores, Manchester.
23,226. Handles for Files, A. R. Bellamy and A. J. Hobson, Manchester.
23,227. Inkwells, E. M. B. Smith, London.
23,228. Recovery of Oils from Clay, &c, S. Crowder, London.
23,229. Fence Advertisement, L. B. Bethell, Epsom.
23,230. Retorts for Distilling Oils, R. V. Horsfall, Manchester.
23 231. Carpet Fastener, A. F. F. Kislingbury, Bristol.
23,232. Clamps, A. E. S. C. L. Classey, Bristol.
23,233. Refrigerators, &c., A. E. S. C. L. Classey Bristol.
23,234. Sugar-cane Mills, W. and H. O. Smith.—(*A. D. Smith, Australia.*)
23,235. Evaporating Apparatus, J. Foster, Glasgow.
23,236. Fixed Shafts Support, H. L. Thomas, Thorpe.
23,237. Sheet Metal and Composite Boxes, W. Orr, Glasgow.
23,238. Thread Spool, A. Conkling, Glasgow.
23,239. Couplings for Railway Vehicles, R. Haub and B. A. Schenck, Manchester.
23,240. Connecting Link for Chains, F. C. Paul, Birmingham.
23,241. Candle-holder, F. R. Koss, London.
23,242. Buckles and Harness Fasteners, R. A. King, London.
23,243. Workmen's Time Recorders, W. P. Thompson.—(*W. Le G. Bundy and The Bundy Manufacturing Company, United States.*)
23 244. Distillation of Water, J. S. Pearson and E. L. Newsome, Manchester.
23,245. Trousers Suspender, R. oh. Flemming, London.
23,246. Raising Sunken Vessels, &c., G. A. Savile Harrogate.
23,247. Pads for Supplying Colour to Stamping Blocks, H. S. Woodyer, Manchester.
23,248. Railway Wagons, C. Hunt, Birmingham.
23,249. Collapsible Tubes, J. A. Ehrenfest and J. C. Martin, London.
23,250. Gauges of Electric Exhaustion, E. S. and E. S. d'Odiardi, London.
23,251. Appliance for Mail-cart Shafts, H. V. Lloyd, London.
23,252. Carving Forks, A. H. Bogle, London.
23 253. Sanitary Dust or Waste Bins, H. J. Adams, London.
23,254. Extracting Pickles from Bottles, J. T. H. Ward, London.
23,255. Protecting Pockets, &c, A. H. Carley, London.
23,256. Stirrups, M. Sleeman, London.
23,257. Filters, D. Richards, London.
23,258. Manufacture of Forks, &c., E. de Pass.—(*La Société Française d'Alliages des Métaux, France*)
23,259. Easels, W. Luker, jun., London.
23,260. Preparation of Smokeless Powders, C. P. Du Buit, London.
23,261. Envelopes for Letters, &c., S. Saw, jun, London.
23,262. Roasting of Sulphide Ores, C. F. Claus, London.
23,263. Attachment for Beer Taps, A. Parmenter, London.
23,264. Mechanically Checking Accounts, P. W. Turquand, London.
23,265. Tobacco Pipes, E. H. and F. H. R. Neville, London.
23,266. Decapping Cartridges, P. R. J. Willis.—(*W. A. Wright, United States.*)
23,267. Railroad Sleeper, P. R. J. Willis.—(*H. Gilmore and H. C. Marlatt, Canada*)
23,268. Toe-sweeper, A. Volland, Berlin.
23,269. Motor applicable to Velocipedes, F. N. Blanc, London.
23,270. Medicinal and Nutritive Compound, G. A. Clowes, London.
23,271. Hydraulic Pump, A. G. Browning.—(*J. W. Anderson, Canada.*)
23,272. Velocipedes, W. T. Wilson, London.
23,273. Stop Valve, C. Davy, London.
23,274. Manufacture of Metallic Peroxides and Caustic Alkalies, L. P. Hulin, London.
23,275. Coal-boxes, A. M. Chambers, London.
23,276. Fasteners for Window Sashes, &c., C. Sears, London.
23,277. Obtaining Motive Power, D. and I. Jones, London.
23 278. Manufacture of Gas, J. M Bosselaar and J. F. M. van den Eishout, London.
23,279. Electrically-propelled Carriages, F. King, London.
23,280. Applying Disinfectant to Dustbins, &c, F. S. Salberg, London.
23,281. Lace Grip, J. Batty, London.
23,282. Washing Machines, G. Viner.—(*H. H. Evans and A. J. Viner, Australia.*)
23 283 Holder for Umbrellas, &c, E. H. Goold, London.
23,284. Continuous Spinning, &c, Machines, G. Laurency, London.
23,285. Packing for Piston-rods, &c, E. A. Bryant, London.
23,286. Mitre Block, C. E Smith and M. Vedder, London.
23,287. Sowing Seeds, W. R. Bowen and T. C. Butler, London.
23 288. Combined Churn and Butter Worker, A. M. Bingham, London.
23,289. Curtains for Windows, &c, S. Townsend, London.
23,290. Wooden Skewer Peg, J. N. Harmer, London.
23,291. Device for Cutting Cotton, B. A. Spaull, London.

*1st December*, 1894.

23,292. Toe-clips of Cycle Pedals, W. T. Cantrill and T. C. Whitehouse, Birmingham.
23,293. Obtaining Gold from Ore Tailings, S. Crowder, London.
23,294. Electrical Lamp, E. Grahame, London.
23,295. Combined Paper Weight, &c., H. Berry, Devon.
23,296. Bed Frame, J. F. Dowling and J. E. Dowling, Co. Dublin.
23,297. Causing Chemical Changes of Gases, N. van der Sleen and A. Schnellen, London.
23,298. Steam Economiser, C. Saville, Harrogate.
23,299 Looms for Weaving Tufted Fabrics, W. Kennedy, Glasgow.
23,300. Holders for Exhibiting Drawings, E. M. Brodie, Glasgow.
23 301. Pneumatic Seats, R. R. Jardine, Birmingham.
23,302. Egg Whisks, W. Johnson, R. Crabtree, and S. Thompson, Manchester.
23,303. Securing Pneumatic Tires to Wheels, J. Boyd, Dublin.
23,304. Hydraulic Lifts, J. S. Stevens and C. G. Major, London.
23,305. Suspenders for Portable Mangers, A. Duncan, Glasgow.
23,306. Pneumatic Tires, J. Andrew, Glasgow.
23,307. Regulating Weft Fork Holder, B. Kay, Darwen.
23,308. Drawing-room Football, J. A. Kennedy, London
23,309. Oil Tanks of Cycle Lamps, J. Parker, Birmingham.
23,310. Manufacture of Envelopes, J. J. Brock, Birmingham.
23,311. Safety Lamps, A. Storey, jun, Newcastle-on-Tyne.
23,312. Button-hole Appliance, S. Chapman, Manchester.
23,313. Padlocks, E. Lawton, Birmingham.
23,314. Fuel Economisers, A. Lowcock, Manchester.
23,315. Fuel Economisers, A. Lowcock, Manchester.
23,316. Water-marking Paper, F. Price and H. G. Gallop, Bristol.
23,317. Hosiery Frames, F. M. Hilscher, Manchester.
23 318. Ball-bearings for Vehicles, J. Schoch-Fisher, Manchester.
23,319. Connecting Hose Pipes, J. C. Hudson, London.
23,320. Method of Tip and Brim Stretching, A. Dyson, Huddersfield.
23,321. Umbrellas, W. Coathupe, Bristol.
23,322. Combined Fruit Knife and Nut Cracker, T. Hirschfield, Manchester.

23,323. Screw-keys, M. Stefani, Glasgow.
23,324. Hermetically Stoppering Bottles, W. Hinchliffe, Wakefield.
23,325. Draw Bar Gear of Railway Vehicles, J. Wallace, Wigan.
23,326. Inking Apparatus, J. G. Schelter and Giesecke, Germany.
23 327. Apparatus for Pistonless Pumps, W. H. Morgan, Birmingham.
23,328. Teaching Mine Surveying, T. A. O'Donahue, Liverpool.
23,329. Golf Club Support or Rest, G. W. Buxton, Manchester.
23 330. Treating Grain Extracts, W. H. Walker, Liverpool.
23,331. Railway Signalling Apparatus, R. M. Richardson and F. Delacour, London.
23,332. Horse Food Rest, J. Lee. Edinburgh.
23,333. Springs, &c., for Cycle Saddles, T. Harvey, Walsall.
23,334. Yarn Warping Apparatus, R. L. Hattersley and S. Jackson, Bradford.
23,335. Music Leaf Turner, J. T. Browne, West Grinstead, Sussex.
23,336. Bed Airer, J. T. and A. F. Browne, West Grinstead, Sussex.
23,337. Appointment Indicators, &c., J. D. Davies, London.
23 338. Carriers for Cash and Letters, J. G. Ingram, London.
23.339. Whist Point Recorder, &c., W. G. Browne, London.
23,340. Securing Paper Capsules, W. F. and A. E. Hunt, London.
23,341. Tobacco Pipes, A. Weekes, London.
23,342. Rotary Printing Machines, J. Michaud, London.
23,343. Tobacco Pipe Stem Cleaners, W. S. Roe, Birmingham.
23,344. Mail or Go-carts and other Vehicles, L. L. Hollier, Birmingham.
23 345 Hair Curlers, T. Thompson and G. Grice, London.
23,346. Belt Fastener, W. H. Cranstone, London.
23 347. Hat and Umbrella Stands, F. T. Hirsch, London.
23,348. Parallel Rulers, J. G. Lister, London.
23,349. Gas Shades, G. Hayes, London.
23,350. Metallic Bungs, E., G., and J. Regnac, Berlin.
23,351. Fire-bar for Boiler Furnaces, R. Lewis, Aberdare.
23 352. Tail Stocks for Lathes, J. Ward, Southminster, Essex.
23,353. Applying Runners to Vehicles, J. Ward, Southminster, Essex.
23,354. Heating Carriages, E. J. Preston and A. B. Gill, London.
23,355. Bodkins, J. R. Green, London.
23,356. Metallic Mining, &c., Props, W. E. Kenway, London.
23,357. Plastic Material, W. White, London.
23,358. Fire-arms, J. Luciani, London.
23,359. Manufacture of Oxycarbon Acids, L. Lederer, London.
23,360. Cooking Ranges or Stoves, K. N. Nenadovitch, London.
23 361. Cycle for Advertising, L. C. Martonfalvy, London.
23 362 Combined Rack and Adhesion Locomotives, R Peacock, London.
23,363. Beetroot Digging Apparatus, L. Frennet-Wauthier, London.
23 364. Oil and Gas Engines, E. T. Bousfield, London.
23 365. Process for Covering Flowers, A. Escroignard, London.
23,366. Pianofortes, H. J. W. Raphael, London.
23 367. Drop-down Guns, H. A. A. Thorn, and W. Bodin, London.
23 368. Tires, C. G. Neat, London.
23 369. Fly Traps, A. Tuffnell, London.
23,370. Manufacture of Caustic Alkalies, L. P. Hulin, London.
23,371. Pistons for Steam Cylinders, D. Kidson, London.
23 372. Hat Ventilator and Guard Reel, B. Richards, London.
23,373. Simultaneous Carbonisation, A. Weil and A. Goutierre, London.
23,374. Covers of Pneumatic Tires, R. Pritt, London.
23,375. Wheels for Cycles, H. P. Madsen, London.
23,376. Furnace-grates, H. and H. J. Warington, London.
23,377. Type-writing Machines, G. J. Lysaght, London.
23,378. Manufacture of a New Kind of Lace, E Davenière, London.
23,379. Beds for Children, H. H. Lake.—(*J. Stuttgard, Germany.*)
23,380. Modelling, R. Wallwork, A. C. Wells, and M. B. Church, London.
23,381. Apparatus for Propelling Cycles, H. Hargreaves, London.
23 382. Tread Surfaces, J. M. and W. Starley, London.
23,383. Covers for Pipes, J. Hewitt and F. R. Baker, London.

*3rd December*, 1894.

23,384. Corset, M. K. Green, London.
23 385. Manufacture of Iron, A. Carter and E. Purser, Manchester.
23,386 Adjustment of Footboard of Mail-cart, C. C. Beetles, London.
23,387. Photographic Printing Frames, H. J., A. S., and G. A. Spratt, London.
23,388. Word-numbering Attachment for Typewriting Machines, H. H. O'Farrell, London.
23,389. Construction of Centrifugal Fans, G. M. Capell, Stratford.
23,390. Hoisting Apparatus, F. J. Eastmead, London.
23 391. Aluminium Golf club Heads, C. Playfair, Belfast.
23,392. Incandescent Gas Lamps, J. Armstrong, London.
23,393. Metallic Fittings for Belts, J. Pailey, Birmingham.
23 394. Securing Terminals to Rods, G. T. Piggott, Birmingham.
23,395. Nail Nipper, &c., J. R. Watts, Sheffield.
23,396. Boiling Apparatus, T. Moore, Bristol.
23,397. Shuttle Checking Motion, J. Kaye and W. Schofield, Huddersfield.
23,398. Electric Batteries, R. M. and A. McDonald, Glasgow.
23,399. Apparatus for Feeding Elevators, W. Johnston, Liverpool.
23,400. Manufacture and Lacing of Boots, &c., J. Cottrell, jun., Bristol.
23,401. Driving Gear of Cycles, R. Reynolds, Dublin.
23,402. Pickers for Looms, W. Muir, Glasgow.
23,403. Desiccated Locust for Cattle Food, W. J. Mackey, Kent.
23,404. Drawing Bags through Warehouse Doors, W. J. Willmore, Liverpool.
23 405. Producing Watermarks in Paper, H. G. Forbes and E. M. Somerville, Bitton, near Bristol.
23,406. Clip for Attaching Jewellery to Show Cards, A. Scott, Birmingham.
23,407. Flushing Cisterns, S. Gratrix, jun., and Brother and H. Brocklesby, Manchester.
23,408. The Plug Pipe, C. Lees, Leominster.
23 409. Felt Hats, R. Robinson, Gee Cross.
23,410. Chambers for Children, C. J. Watts, London.
23,411. Puncture-proof Material for Tires of Cycles, M. Lyons, Cork.
23,412, Grooving Machine, J. Cook, W. Swarbrick, and H. Bernard, Lancashire.
23,413. Automatic Balancing Toe clip, G. Lawler, London.
23,414. Hair Pins, N. F. Dean, Liverpool.
23,415. Precipitation Tanks, J. S. Pickering, Birmingham.
23,416. Tramcar Wheels and Axles, J. Willoughby, London.
23,417. Mechanically-driven Shears, G. Bowmar, London.
23 418. Bedsteads for Invalids, A. M. Douglas, Birmingham.
23,419. Brakes, G. L. Hillier, London.
23,420. Brush-making Machines, C. Rehse, London.
23 421. Combinations for Ladies, &c., K. M. Moran, London.
23,422. Velocipede Mechanism, W. J. and E. Freeman, London.
23,423. Closing Devices for Doors, G. A. Farini, London.
23,424. Fastener for Wearing Apparel, K. Brighten, London.
23,425. Last-socket, W. Whiffin, London.
23,426. Hermetically Closing Boxes, A. W. Marshall, London.
23,427. Sewing Machine, T. J. Roome, London.
23,428. Taps, J. S T. Beveridge, London.
23,429. Ventilating Manholes, E. C. Peirson and T. Smith, London.
23.430. Apparatus for Polishing Knives, W. Kiersch, London.
23.431. Mortice Locks and Latches, W. Bywater, London.
23 432. Garments, W. J. Gray, London.
23,433. Brooms, G. Rochlitz, London.
23,434. Railway Points and Signals, W. S. Frost, London.
23,435. Colouring Matters, C. D. Abel.—(*The Actien Gesellschaft für Anilin Fabrikation, Germany.*)
23 436. Water-tube Steam Boilers, E. Petersen, London.
23.437. Boats, &c , W. H. F. Gerald, London.
23,438. Manufacture of Acetone, R. Jurgensen and A. Bauschlicher, London.
23,439. Pedal Bearings for Cycles, J. Billebrandt, London.
23.440. Axle Bearings of Cycle Wheels, J. Hillebrandt, London.
23,441. Galvanic Batteries, J. C. and G. Fuller, London.
23 442. Closing Lead Pipes, J. J. Burton and S. Cooper, London.
23 443. Steam-tight Packing, A. J. Boult —(*H. Engler, Germany.*)
23,444. Targets, A. Mantel-Rieter and E. Meyer, London.
23,445. Tip Carts, B. Norrington, London.
23 446. A Carrier, I. J. Gudendag, London.
23,447. Middlings Purifiers, W. H. Ince, London.
23,448. Extinguishing Flames in Burners, H. Terrett, London.
23,449. Measuring Dimensions of Eggs, C. Bird, London.
23 450. Canning Lobsters, &c., L. Wutzburg, London.
23,451. Apparatus for Measuring Liquids, J. Tabel, Germany.
23,452. Alarm of Approaching Trains, R. Page, Shropshire.
23,453. Cycles, A. Rousselle, London.
23,454. Water-gas Apparatus, O. N. Guldlin, London.
23,455. Oil-feeding Apparatus, O. N. Guldlin, London.
23,456. Respirators, J. A. Wittard, London.
23,457. Mounting Spinning Baits, W. and J. J. Hardy, London.
23,458. Hernia Trusses, W. W. Turver, London.
23,459. Heat Resisting Boot, L. N. Thierry and T. E. Penrose, London.
23 460. Gangway Rollers, R. Simpson, Westminster.
23,461. Sack-holders, J. Marshall. —(*H. Graepel, Austria.*)
23,462. Automatic Funnels, R. A. Brown and F. S. Bond, London.
23,463. Car Fender, W. Hofmeister, London.
23,464. Extension Tie Plates, W. R. Funk and A. G. Henry, London.
23,465. Incubators, J. Vaughan-Sherrin, London.
23,466. Track Clearer for Tramways, G. Beit, London.
23,467. Closets, N. Hessler, London.
23 468. Apparatus for Heating Purposes, G. Kern, London.
23,469. Flushing Apparatus for Closets, J. T. Tennant, London.
23,470. Hair-pins, A. Knippenberg, London.
23,471. Shifters of Linotype Machines, The Linotype Company, C. L. Ireland, and J. Plaice, London.
23,472. Telephony, C. Adams-Randall, London.
23,473. Water-closets, H. E. Baden, London.
23,474. Controlling Mechanism for Gun Turrets, R. Wright, London.
23,475. An Automatic Rein Holder, N. Behrens, London.
23,476. Skirt, I. A. Margesson, London.
23,477. Game, H. R. Troup, London.

*4th December*, 1894.

23,478. Button Fastener or Attachment, J. Chalke, London.
23,479. Strainers and Tea-pots, F. W. Bettall, London.
23,480. Combined Mat and Electric Alarum, J. J. Pye, London.
23.481. Tube Stopper, J. R. Reedman and J. Scott, London.
23,482. Sash Attachments, F. Bitchmough, Liverpool.
23.483. Mixing India-rubber, A. G. Brookes.—(*J. E. Davis, United States.*)
23,484. Screw-covers and Wreath-carriers, W. Nicholls, Birmingham.
23,485. Blind Cords, H. Wardingley and W. M. Cooke, Sheffield.
23,486. Accumulators, F. L. Berners and F. Griffin, London.
23,487. Boxing Gloves, C. Playfair, Belfast.
23,488. Combination Penholder, W. B. Robinson and C. L. Wilkinson, Manchester.
23,489. Steam Generators, H. Wilcke, Liverpool.
23,490. Furnaces, R. Evans and T. W. Jones, Liverpool.
23 491. Taps or Valves for Barrels, C. Preston, Manchester.
23,492. Rectal Dilator and Irrigator, F. Trinder, London.
23 493. Kindergarten System, &c., H. Richardson, Bradford.
23,494. Electric Current Indicators, S. P. Thompson, London.
23,495. Cigarette Holders, D. Thomas, Llanishen.
23 496. Fastening Retort Mouthpieces, G. Winstanley and G. H. Robinson, Coventry.
23,497. Fire Back, E. Hulley, Ashton-under-Lyne.
23,498. Securing Clothing to Flats, J. T. Scowcroft, London.
23,499. Tips for Umbrellas and Sticks, J. Wright, London.
23,500. Pincers for Dentists' Use, J. Burwell, Colwyn Bay.
23,501. Ankle Protector, J. R. Jones, Llanon *viâ* Aberystwith.
23,502 Plate Coils for Furnaces, J. Paterson, Workington.
23,503. Wire Mattress, G Lane, T. M. Hewetson, and H. J. Lane, Birmingham.
23,504. Golfers' Hand-bag, E. A. Jones, Dudley.
23,505. Electric Light Fittings, J. McFarlane, Glasgow.
23,506 Waterproof Feet Coverings, J. Wilson, Manchester.
23,507. Saddles for Velocipedes, &c., W. Lowe, Leicester.
23,508. Fastening Blinds on Rollers, J. Whitehead, Birmingham.
23,509. Phantom Baits, G. Forrest, Glasgow.
23,510. Burglar-proof Locks, A. Dalziel, Glasgow.
23 511. Applying Tooth-powder, R. M. and J. S. Sanger, Glasgow.
23,512. "Collar" for Horses, T. Staines, J. Leadbeater and A. Preston, Leeds.
23,513. Woven Wire Mattresses, D. Hewitt, Birmingham.
23,514. Securing Broom Handles, J. S. Walford, Birmingham.
23,515. Cycle Lamps, R. W. Neale, Birmingham.
23,516. Adjustable Joint, J. Brookes, H. J. Brookes, and P. L. Renouf, Smethwick.
23,517. Games, E. H. Durnford, Hawley.
23,518. Recovering Gold from Ores, W. Fairweather. —(*G. W. Webber, United States.*)

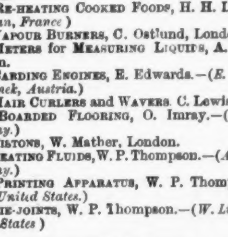
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**525,697.** Winding for Drum Armatures in Dynamo Machines, *R. Eickemeyer, Yonkers, N.Y.—Filed March 9th*, 1892.

*Claim.*—The combination with the armature drum, of a group of independent or individual coils, each of which has a long and a short side lying along the periphery of the said drum, and inclined ends lying across the ends of said drum, the several inclined ends of the several members of the said group at either end of said drum crossing that end of the drum in two radial lines connected by a line substantially parallel to the periphery or edge of the core, and the said several members being separated on the periphery of the drum, substantially as described.

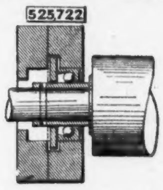
525697



**525,722.** Bearing for Clothes-wringers, *A. R. Sauters, Cleveland, Ohio.—Filed May 23rd*, 1894.

*Claim.*—The wringer frame, in combination with the roller shaft and the horizontal sleeves fixed thereon to take the wear, the bearing block E having a groove about its inside for anti-friction balls, the anti-friction balls in said groove, and the plate G confining said balls, and flanges extending laterally from said plate and engaging in the guide ways in the wringer frame, substantially as set forth.

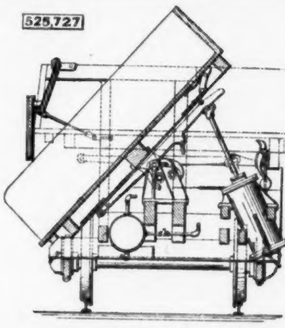
525722



**525,727.** Dumping Car, *E. A. Trapp, New York, N.Y.—Filed February 27th*, 1894.

*Claim.*—In a dumping car, the combination of the truck and supporting frame thereon, the swinging car body, the pin and slot connections between said supporting frame and said swinging car body, one or more pins mounted on one of the two last-mentioned elements of the combination, to wit, the supporting frame or the swinging car body, and curved jaws mounted on the other of the said two last mentioned elements and embracing the above described pin or pins, said pin or pins and co-operating jaws, together with the pin and slot connection, positively controlling the motion of the car body in dumping, substantially as described.

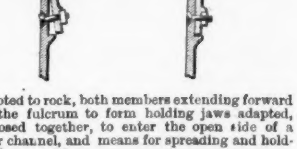
525,727



**525,756.** Joint for School Furniture, *G. M. Bennett, Grand Rapids, Mich.—Filed June 29th*, 1893.

*Claim.*—In a furniture joint or fastening of the character described, the combination with the fixed member, of a movable member having a fixed, in contradistinction to a movable fulcrum thereon on which it is adapted to rock, both members extending forward beyond the fulcrum to form holding jaws adapted, when closed together, to enter the open side of a groove or channel, and means for spreading and holding said jaws apart.

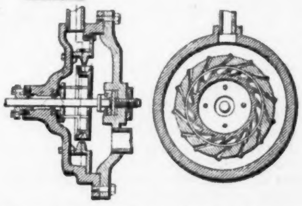
525756



**525,793.** Rotary Engine, *J. F. McElroy, Albany, N.Y.—Filed January 16th*, 1894.

*Claim.*—(1) In a rotary motor, a wheel comprising a solid metal rim having a series of pairs of inclined pockets therein, the pockets of each pair being divided by a tapering ridge, and a circular steam ring having a circular series of jet nozzles extending therefrom into close proximity to and in line with the tapering dividing wall of the pockets, whereby a free passage for the steam is formed at the sides of the nozzles, substantially as described. (2) In a rotary motor, a wheel having a series of peripheral pockets therein arranged in pairs, a tapering dividing wall between the pockets of each pair, and a flat inclined cut-away portion M, at the rear of the wall, and a circular series of protruding jet nozzles arranged in proximity to and in line with the said wall, substantially as described.

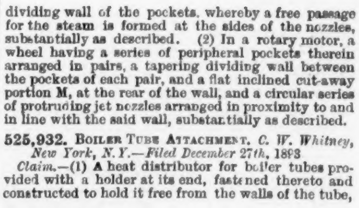
525,793



**525,932.** Boiler Tube Attachment, *C. W. Whitney, New York, N.Y.—Filed December 27th*, 1893

*Claim.*—(1) A heat distributor for boiler tubes provided with a holder at its end, fastened thereto and constructed to hold it free from the walls of the tube, substantially as described. (2) In combination with a tube protector, a heat distributor having one end divided and attached to said tube protector, substantially as described. (3) As a new article of manufacture, a combined tube protector and heat distributor constructed and arranged substantially as shown and described.

525932



Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided for our breakfast and supper a delicately flavoured beverage which may save us many heavy doctors bills."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, by Grocers, labelled, "James Epps and Co, Homœopathic Chemists, London.'

## LIGHT RAILWAYS.

The Conference on the subject of light railways, proposed by the Board of Trade commenced its sittings on the 6th inst., under the presidency of Mr. Bryce. So far as space permitted, the meeting was representative of the various interests concerned, but it could not be said to be fully representative, inasmuch as the boardroom of the railways department of the Board of Trade could not hold half the persons who desired to attend.

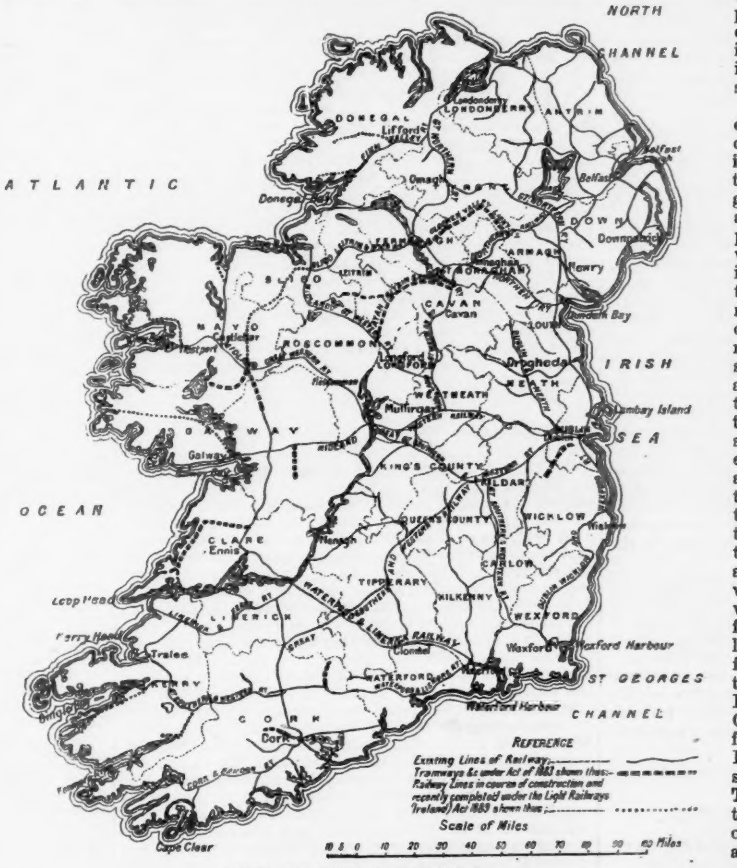
The meeting was held by invitation from the Board of Trade, and amongst those who attended were:—The Duke of Sutherland; Lord Thring, Lord Edmond Fitzmaurice, and Mr. H. Hobhouse, M.P. (Association of County Councils); Sir Albert Rollit, M.P., Sir Bernhard Samuelson, M.P., Sir A. Hickman, M.P., and Mr. F. Corbett (Association of Chambers of Commerce); Lord Claud Hamilton, M.P., Mr. J. C. Bolton, and Mr. W. L. Jackson, M.P. (Railway Companies' Association); as well as Major Rasch, M.P., Mr. S. Storey, M.P., Sir Benjamin Baker, Mr. Channing, M.P., Earl Cathcart, Sir E. Carbutt, and many others. Mr. Bryce, in welcoming those present, said that the Conference was called not to place any views of the Department before them, but to ascertain the views of those invited to it. The depression in agricultural matters had been one motive for calling a conference on the subject, which many persons felt might offer some amelioration for a state of things which had continued for some years past, and amongst the remedies suggested was the opening of better means of communication between rural districts, following the example of Belgium, France, and other countries. It was now fifty years since most of the great trunk lines were built, and comparatively little had been done towards extending the means of locomotion to the less populous districts. Notwithstanding that the mileage of the country had increased in the interval by 40 per cent., enough had not been done for the minor means of locomotion, especially in the conveyance of produce, while there was increasing evidence on the part of the public that accommodation of the kind was wanted. The Board of Trade had not been indifferent to this demand; but the Department was restricted by statutes and usage, and it would require the sanction and permission of Parliament to enable it to make any departure from the rules by which it was guided in approving schemes of railway construction. It must always be led by public opinion; and he invited the views of the Conference on two heads of inquiry—as to agriculture and congested populations. If the cost of transport was an element in the competition of Danish and French produce, it was a matter that ought to meet with their earnest consideration. On the industrial side they should consider whether they could enable workmen in the towns to live in the healthier suburbs by cheapening the cost of transit between the crowded city and the open country. Then they had also to consider the cost of construction: whether the lines could be built more cheaply; and also whether parliamentary powers could be obtained at less expense than at present. It was clear that if they wished to cheapen the normal cost of railway building they must drop something, either in speed, or safety and comfort of passengers, or of convenience in the transport of goods; and this was a matter in which the Department must follow and not lead public opinion.

The chairman then referred to the requirements which the Board of Trade might dispense with, but said very clearly that the subject of aid granted by the State was not worth discussion, as that was quite out of the question. He believed that there was a real need for cheaper and more extended means of communication, and that the enterprise would pay if the lines could be made at a lower rate than at present. If the Board of Trade had reason to believe that public opinion was ready for a forward move in this matter, there would be on the part of that Department no want of earnestness or activity in promoting such an object. He suggested that it would be well to wind up the proceedings of the Conference by appointing a committee, which should present the report to the Board of Trade before the end of January, in order, if thought necessary, that legislative action could be taken in the next session of Parliament. A discussion then followed, in which several of those present joined.

After the adjournment for luncheon, the chairman proposed that before resuming the general subject the committee of which he had spoken should be nominated. This was done. The Duke of Sutherland proposed, and Lord E. Fitzmaurice seconded the selection of the following gentlemen, among others, as a committee to inquire into the question at issue:—Sir Michael Hicks-Beach, Sir B. Samuelson, Sir A. Hickman, Mr. W. Jackson, Mr. Beachcroft, Lord Claud Hamilton (Colonel Makins to act in his absence), Lord Cathcart, Sir C. Boyle, Mr. Hopwood, Lord Thring, Mr. W. Meik, Mr. H. Hobhouse, Mr. Ackworth, Mr. Storey, Mr. Humphreys Owen, Sir B. Baker, Sir A. Rendel, Sir A. Clarke, Mr. A. Siemens, Lord E. Fitzmaurice, Mr. Sellon, Mr. Channing, Sir A. Rollit, Mr. Wain, and himself, the committee to meet at once, so as to present their report before the end of January. Further discussion followed, much information being afforded by Mr. W. L. Jackson, M.P., and General Sir R. Sankey, President of the Irish Board of Works, on the construction and working of light railways in Ireland. Ultimately the Conference was adjourned till January, 1895.

A *résumé* of the results of Government and local government efforts in Ireland for some ten or eleven years will probably throw some light of experience on the proposals which may be broached at the resumption of the Conference. From the commencement of the railway system the British Government has scarcely even contemplated State aid to railways in Great Britain; but from a period as early as 1836 there were proposals to assist Irish lines, if not to construct them, by the State. Government aid was sought and obtained in many instances, and several sums were advanced out of the Consolidated Fund for the construction of Irish railways from 1842 to 1847. In the latter year, in consequence of the famine of 1846, large advances were made; and up to 1893 £4,000,000 or over had been advanced, most of which has already been repaid, and no default in interest or repayment has occurred.

There has also been much assistance given to Irish railways in their earlier stages, when some of them were little better than what would be called "light railways" now, by landed proprietors interested for their own sakes in the construction of the earlier lines; and the system of guarantees secured upon the rates by counties and baronies has been largely employed to aid in raising the required capital. In some cases these local guarantees were limited to a maximum sum in each year, in others to a maximum rate on the ground valuation. In some, the revenue of the line has much reduced these rates in aid, whilst in others there has been no diminution of the tax. The total amount thus guaranteed for what may be called main lines is a little over a million sterling.



LIGHT RAILWAYS IN IRELAND

When, however, we come to 1880, the construction of main lines may be said to have ended; and the Government, under various ministries, came forward to help the promotion of what in France would be called "vicinal" railways, ending with the well-remembered Light Railways (Ireland) Act of 1889.

In 1880 the "Relief of Distress Amendment Act" was passed, by which the Treasury was allowed to lend on favourable terms, and on the security of baronial guarantee, to some lines specified in the Act. It was found, however, that but little use could be made of the powers granted under this law, and in 1883, the "Tramways and Public Companies Act" gave, subject to the control of the Commissioners of Public Works, Ireland, certain facilities in the procedure for obtaining powers, and instituted the principle of building branch lines with capital guaranteed, half by the Imperial Government and half by the baronies interested. Under this Act about 300 miles of railway have been constructed, as shown on the accompanying map, of which more than 200 are 3ft. gauge, the rest on the Irish standard of 5ft. 3in. They have, on the whole, paid somewhat more than their working expenses, so that less than the guarantees on capital account has been called for; but they cannot be called "light railways," for in generally easy countries they have cost £5000 a mile, and they were always made to connect some town or small port with the general system, and not, therefore, "agricultural railways" in the strict sense of the word. The net result of this Act has been that 288 miles of railway—fifteen distinct short lines—have been built for about £1,190,000 raised by guarantee of 2 per cent. by the Government, and from 2 to 3 per cent. by the baronies. In almost every case the Treasury has had to pay its whole contribution, and the barony most of its liability.

In 1889 came the so-called "Light Railways (Ireland) Act," though why it was so called it would be hard to say, except for the same reason that the Romans gave its name to a grove.

The report of the Commissioners of Public Works in Ireland gives the following account of the inception and working of this Act, under which 240 miles of line, nearly all of standard gauge, have been laid at a cost of about £7500 per mile, of which Government has contributed by grant about two-thirds:—

"The Royal Commission on Irish Public Works, of which Sir James Allport was chairman, reported in 1888 that the results of the Act of 1883 had not been such as had been hoped and expected. They attributed this comparative failure—(1) To the cumbrous, and consequently expensive, procedure under the Act; (2) to the form which the guarantee takes in practice, no payment being capable of being made for any half-year till several months after its close, and the Government contribution, from its indirect character, giving practically no additional value to the stock; (3) to the great liabilities imposed upon the district, not only for interest, but for working expenses; (4) to the great responsibility thrown upon the Privy Council; (5) to the fact that no existing railway company could promote a line under the Act; (6) to the encouragement given by the executive Government to the promotion of lines on the 3ft. gauge. The Commission also passed some general criticisms on the principles of the Act based on the want of independent control throughout the proceedings, the constitution of the public bodies, by whom the guarantees were given, and the danger that such lines might become a means of investing money simply on the strength of the guarantee, the holders of the stock having no personal concern in the success or efficient working of the line, or even in its proper construction, inasmuch as the interest on their capital is in any case secured to them under the guarantee.*

"The Royal Commission come to the conclusion (1) that railway extensions cannot be made without State assistance in the parts of Ireland in most need of them; (2) that if such assistance were given it should be given in the clearest and most direct way, consistent with the preservation of local responsibility, and with the existence of some provision for its ultimate discontinuance, and they, therefore, recommended that the Government should grant to the constructors of any approved line 3 per cent. on the necessary capital, and that the district should guarantee in addition the equivalent of a rate of sixpence in the £1 on the annual rateable value, this local contribution being allotted in the first instance to meeting any excess of working expenses above the income of the line, and subject to this to the reduction of the payments by the Government under the guarantee. As regards the gauge they recommended that wherever possible the gauge should be the standard gauge, and that the lines should be 'light railways.' The light railways recommended were:—From Downpatrick to Ardglass; from Letterkenny *via* Kilmacrenan, Cresslough, and Dunfanaghy to Cross Roads; from Stranorlar *via* Glenties and Ardara to Killybegs; from Ballina *via* Killala to Belmullet; from Galway to Clifden *via* Oughterard; from Killorglin to Valentia; from Skibbereen to Baltimore; from Kinsale Station to Kinsale Harbour; short branches at Bantry and Dungarvan. These recommendations are in addition to lines which have been, since the date of the report, constructed under other arrangements.

"In the session of 1889 the Government introduced the Light Railways (Ireland) Bill, the object of which was to give effect to some of the recommendations of the Commission. It provided that the Lord-Lieutenant in Council might from time to time declare that it is desirable that light railways should be constructed between certain places for the development of fisheries and other industries; but that, owing to the circumstances of the district, special assistance from the State is required for their construction. The State assistance was to be derived (*a*) from the balance of the annuity of £40,000 given by the Tramways and Public Companies Act, 1883; (*b*) from a capital sum of £600,000 to be provided by Parliament; (*c*) from an additional annuity of £2000. Owing to Parliamentary exigencies, the Bill, as finally passed, was confined practically to these provisions and to the incorporation of the procedure of the Tramways Acts, and none of the desirable amendments in previous legislation were included. The Act was to apply only (*a*) where the promoters of the light railways are an Irish railway company having a railway open for traffic; or (*b*) where the promoters have made an agreement approved by the Treasury for the maintenance, management, and working of the light railway by such railway company; or (*c*) where a baronial guarantee was given for the payment of dividends upon a portion of the capital pursuant to the provisions of the Act of 1888. The aid of the Treasury might take the form of a capital sum or of an annual payment, or partly one and partly the other, and the capital sum might be a free grant or a loan, or partly one and partly the other. The adjustment of the two forms of aid — annual payment and capital sum — so as not to exceed the limits of the Treasury assistance already stated, was directed to be made on the basis of 3 per cent."

---

* This is indeed the case. These Government and baronial guaranteed stocks are held at a considerable premium by investors who have no interest in the railways, but simply as so much Government funds.

We have given the principal statistics of the railways constructed under the Act of 1883. It is too early to judge of the results attained under the Act of 1889, but it may safely be taken that scarcely one of these lines would have been made by capitalists for profit. In most instances they will benefit the localities through which they run and the main lines which they feed; but the reason why of some of them is hard to find out.

. So far, therefore, as the Irish experience is of use, it tells us that some 500 miles of extensions of railways have been made, at Government cost, in the last ten years. They have not been light railways, having cost between £6000 and £8000 a mile in always a reasonable country. More than half of them have come into working; for three or more years very few have paid more than working expenses, very many less.

The experience in Belgium, as given in a very concise report by Major Addison, R.E., to the Board of Trade this month, is in many respects more pertinent to the conditions of the proposed aid to light railways in England in aid of agriculture, &c., but in some other respects it falls short of possibility in this country.

He tells us that no less than 730 miles of railway have been constructed in Belgium during the last eight years with capital, the interest and sinking fund of which—3½ per cent.—has been guaranteed, one-fourth by the Government and three-fourths by the localities. Scarcely any of the capital has been found by private subscribers or persons interested in the lines; yet they are now paying as a whole 2·8 per cent. out of the 3½ per cent. for interest and sinking fund, over and above working expenses. The demand for them also increases; forty miles more are in construction, and about 900 miles are projected. They are "vicinal" lines in the true sense of the word; 615 miles are of 1 metre guage, 125 of 1·067 metre, to suit the Netherlands gauge, and only 30 miles of the 4ft. 8½in. They cost, all found, under £2700 a mile. This sounds very well for "light" railways, but there are other sides to the picture.

First of all these lines are, almost without exception, laid beside or upon the sides of high roads, of which they must practically occupy at least 10ft. wide, for the public are warned not to approach nearer than within 5ft. of the railway.

Now, it is hardly necessary to say that the English and Scotch high roads could not be subjected to this kind of treatment; they are not straight enough, nor wide enough, nor generally level enough; therefore our "vicinal" lines must be railways through the country, and not steam tramways. But even a stronger reason for not laying unfenced railways beside our roads is the very high mortality caused by this system of working. These seven hundred and odd miles of Belgian railways killed in 1893 twenty of the Belgian public who were *not* passengers, and five who were; they did not kill any railway servants, and only injured three. None of the accidents to passengers were the result of collisions or derailments, therefore they were most probably all simply cases of persons run over. Now with this testimony before him we should not be surprised to find Mr. Bryce or any of his successors strongly objecting to reduce the standard of safety required by the Board of Trade down to the Belgian level.

The gradients allowed also, up to 1 in 20, and the curves down to 1½ chains radius, would be a considerable relaxation of our practice for passenger lines; and it is to be remarked that these are properly passenger lines, three-fourths of the receipts coming from that source.

From the above considerations it is clear that our "vicinal" lines must follow more the type of the Irish light railways than the Belgian, and that we cannot hope to construct anything on so cheap a scale as that adopted in the latter country.

## THE IRON GATES OF THE DANUBE.

By BELA GONDA, Chief of the Department of Navigation of the Interior.

(*Concluded from page 464*)

CONSIDERING the great and international character of the works, it was thought proper that they should be inaugurated in the presence of all the various interests, and the ceremonial took place on the 18th September, 1890, the works being commenced by the blasting of the peak of Greben. To commemorate this day, the contractors cut a memorial table in the wall, on the Hungarian shore over the rock Alibeg, with the following inscription:—"These works, sanctioned by the XXVI. Law of 1888, and destined to remove the navigation hindrances at the Iron Gate and other cataracts, were begun in the reign of the Hungarian king Francis Joseph I., in the time of the prime minister Count Julius Szapàry, by the minister of commerce Gabriel Baross de Bellus, on the 15th September, 1890. God bless this work and its creators."

The building of dykes at the Greben and at the Iron Gate was commenced at the same time. The material resulting from the cutting a width of 150 metres of the Greben is built into the training dyke of the Greben-Milanovacz. This important work was rendered more difficult by the circumstance that the mount Greben runs steeply to the edge of the channel. But this difficulty was soon surmounted. The cutting began on both sides of the mount Greben at several heights at the same time, and for the easier transport of the spoil, a tunnel was made through the peak of the Greben. The removal of the rock was effected by great mines filled with 2000 to 8000 kilos. of explosives—carboarotin, haloxilin, and dynamite. From the loosened material, the stone corresponding to the conditions stipulated in the contract was picked out and transported to the workyards and over the dyke on railways in wagons. On the way its weight was taken, and afterwards it was thrown into the body of the dyke. From the weight of the stones used—on the basis of previous exact and often confirmed measurings—the cube of the utilised stone is calculated, and the sums are paid to the contractors in conformity with the prices stipulated in the contract.

But only that part of the dyke is built in this manner, which starts from the shore; on the other parts the stone is transported on boats, where the cube of the material is exactly fixed. The stones are thrown from the ships into the projected line of the dyke by manual labour, the work being carried on at several points.

The dykes of the Iron Gate are built entirely by the aid of railway, and the material is transported in long trains on rails laid on the sections of the dyke, and it is thrown from the wagons into the corresponding profiles of the dyke. All wagons are weighed as the trains are running to their destination. The employés of the technical bureau being present at the loading of the wagons, certify the quality of the material; a controller of the bureau takes the weight of the load, and another certifies that the load was duly built into the dyke.

The material of the Iron Gate Canal consists of limestone mixed with slate beds. The extraction of this material is done in a simple and expeditious manner, and in such great quantities that there were days, even months, when the quantity extracted reached 1000 cubic metres per day. The bottom of the canal is provided with a net of railways, and long trains carry the extracted material to the shore, whence the materials which are to be used for the dykes are transported again over the dykes, and there they are built in, and the rest serves to fill in the channel parts and depths behind the right dyke of the canal.

On those parts of the canal which could not have been stopped in this manner American boring-machines—system Ingersoll—placed on rafts will be employed to deepen the bottom, and the rocks will be blown out by dynamite placed in the bore-holes, while for the removing of the extracted material dredges are applied.

The canal to be dug at the Iron Gate is the most prominent and interesting part of these works; but, in point of view of technical difficulties, it is not the canal which constitutes the most interesting part of the works, it is the deepening of the rocky bottoms of the canals to be established in the open river through the cataracts. The rocky masses to be extracted and taken away from the channels to be established in the cataracts of the Stenka, Kozla-Dojke, Izlasz, Tachtalia, and Jucz, are forming a total of 160,000 cubic metres in round numbers; and this all must be operated under the water, in different depths, in currents excessively swift, and forming falls and whirlpools. A similar work with such difficult conditions was never executed. The extraction under the water executed at Bingerloch on the Rhine was less important, and operated quieter water; as for the technical difficulties, we cannot compare it with these works, however similar they may look. The extractions under the water executed on the Saint Lawrence above from Montreal can be compared with our large works, but there the circumstances were more favourable, because they had not to struggle against the excessive and unequal velocities of the current against the violent falls, as at the cataracts of the Lower Danube.

Thus, the arrangement of the works, the just choice of the working engines under such favourable and difficult circumstances, demanded profound reflection, great circumspection, and professional knowledge.

The ordinary modes of the depth measuring, viz., with poles and ropes, were insufficient; more exact instruments were looked for, and the contractors succeeded in obtaining at the Budapest Dockyard, Danubius, the depth-measuring boat.

The depth-measuring ship consists essentially of a horizontal floor, fastened on iron pontoons, which is provided with a slot for each metre, and above two slots two measuring wagons running on rails are placed. The measuring wagon is so constructed that its four corners form exactly the corner points of a square metre, and in these iron pipes, with rods, are applied between the gears in such a manner that they are to be plunged into the splits to the bottom of the channel, and the water depth, viz., the bottom height can be precisely read off at the upper part of the iron pipe. The depths can be measured in all positions of the ship, viz., at four points, a metre distant from each other.

The floor of the measuring ship being 9 metres wide and 16 metres long, the ship placed on a certain point can measure at once a space of 200 square metres, and shows the depth in a regular interval of 1 metre. When the measuring wagon has run down the rail it can be switched by using a turntable to the following rail, and the measurement can be continued in such a manner in the length of the next part. The fixing of the measuring ship on the due place of the canal to be deepened is marked by signs. The floor of the ship corresponding to a length of 20 metres, the canal is divided by the flags—signs—on the shore into sections of 20 to 20 metres each, and these are fixed in a similar way lengthways on the boat. Broadways, the boat is divided into sections of 10 to 10 metres, which comply with the width of the canal to be constructed. As these canals will be 60 metres wide, the depth measurement, for sake of safety, is extended to a width of 70 metres, viz., to seven positions of the boat.

The depth measurements are executed independently of the changing water line mark, the height above the sea being fixed. The rail placed in the centre of the ship is fixed by exact measures executed by two instruments from the shore, showing in every position of the ship the height above the sea. Besides this, the formation of the bottom is marked, on the basis of the surveyed points, in a graphical manner, so that the condition can be seen at a glance. Such exact determination of the depth guarantees that the canals to be cut through the cataracts were really carried out with the projected dimensions.

The loosening of the rocks to be removed under the water is executed by breaking and blasting, while the loosened rocks are taken out with spoon-and-bucket dredges and with Priestman excavators. The breaking machines were constructed after the system of Lobnitz, a Scotch shipbuilder, and were made partly at Messrs. Lobnitz' works, Renfrew. The construction is very simple, and is based purely upon the free fall. For the breaking an iron chisel is employed, which is 9 metres long, square in form, is 15·75in. square in the centre, 16·5in. square at the upper end, weighs 8·5 tons, and in the centre of the lower end a steel bill is fitted. On the upper end are holes for lifting attachment.

This chisel or crusher is mounted upon a vessel with a stage of a height of 12 metres. This stage or framework is placed in two of the vessels over a square hole in the centre of the hull, while on the third it is placed upon two coupled vessels. These vessels were illustrated in THE ENGINEER of the 20th April last, page 332. The ships are of wood, and are equipped with steam anchoring and levelling gear. The working of this machine is very simple. The boats are placed in the centre of the canal to be dug, and fastened by four anchors. When the crusher has smashed the rocky mass to the required depth, which is marked on the crusher chisel, the boat is moved by the steam winches towards the side, and when a strip of half a metre is cut off, the boat advances on the anchor chains to attack the following strip.

For blasting the rocks, boring machines are employed, such as have done good service for many years on the river Saint Lawrence. One of these was also illustrated in THE ENGINEER. There are three or four movable borers fitted to a frame on a wooden boat, which can be, by the help of four legs, raised above the level of the water in order to protect the boat against the movements of the waves. These borers are on the Ingersoll system, driven by steam, and are raised out of water by hydraulic cylinders. Every borer is placed in a pipe provided with narrow slits. This pipe is pressed against the bottom so that the current should not trouble the movement of the engine. Every pipe is, moreover, provided with a strong wire ties, so that the current does not affect the borer which can be maintained vertical.

An automatic Worthington pump is used for raising the frame of the borer by hydraulic pressure, and is supplied by the boiler which drives the borer. The boring and blasting of the rocks under the water with this floating boring boat are executed in the following manner:—Firstly, the survey boat establishes exactly the section of the canal which is to be blown up. The boat bearing the borer is placed at the lower edge of the section, and is anchored. The four supporting frames are lowered to the bottom. After this the borer is placed over the points which were previously determined, and the height of which is known, so that the depth to be attained is easily found. The borer pipes are lowered, the pipe to the bottom, and the borer descends into the pipe as far as the bottom, and the borer set to work.

When the bottom is bored to the required depth—which, in consequence of the conical shape of the hole left by the blasting, must be taken always deeper than the intended mean depth of the canal—the hole is washed out with a strong flush of water in order to clean it, then the charge of dynamite is introduced through the pipe and provided with a fuse, the dynamite being so heavy that the waves cannot carry it away. The above-mentioned slot is provided in the pipe so that the fuse can pass out. When all the holes are bored on the section corresponding to the position of the boat, and all the holes are charged, the fuse is connected with the electrical battery, the boat is lowered into the water, and is withdrawn to 10—15 metres, and then the mines are exploded. After this they begin the boring on the following strip till the whole is blasted.

It may be mentioned that with a blow of the Lobnitz chisel 0·0307 cubic metre of rock is removed, while the blasting of a bored hole loosens 2·50 cubic metres of rock. Experience has proved that the Lobnitz boats work with advantage when the average height of the rock to be removed is not more than 1 metre, while the boring boats are working with advantage in beds which are thicker than 1 metre.

The average work of the crushing machines and boring ships per day was, in 1892 and 1893, as follows:—

| | 1892. Cubic metres. | 1893. Cubic metres. |
|---|---|---|
| One crusher (Lobnitz) | 12·5 | 73·4 |
| Two crushers | 31·9 | 75·5 |
| Three crushers | 28·2 | 73·7 |
| One boring boat | 18·2 | 77·6 |
| Two boring boats | 27·2 | 66·1 |
| Three boring boats | 19·9 | 75·9 |
| Four boring boats | 12·5 | 99·6 |
| Five boring boats | — | 28·5 |
| Total | 150·7 | 477·0 |

And this has increased with the progress of the work.

The material loosened by blasting or crushing is taken out by dredges. The dredges employed on the Lower Danube are partly of a fork-grab form of Priestman excavators, partly of a spoon or bucket form; for some special works a very large dredger with buckets, which excavates large quantities of rock without difficulty. One of these was illustrated in THE ENGINEER of the date above given.

This dredge was constructed at Renfrew, Scotland, in the works of Messrs. Lobnitz; it is 40 metres long, 10 metres wide. The vessel is of very strong construction, on account of the large engine and heavy stresses upon dredger. There are two steam engines, one of 200-horse power, the other of 50-horse power. The construction of this dredge differs from the other dredges only by its large dimensions, except that it has a screw propeller. By this it propelled itself from the works in Scotland, traversed the canal, the Atlantic Ocean, the Mediterranean, the Bosphorus, and the Black Sea, and safely arrived at the cataracts of the Lower Danube. In order to appreciate this passage, we must mention that the ship—being designed for special excavating work—has a flat bottom and flat stem, and a draught of only 7ft. The passage occupied forty-five days.

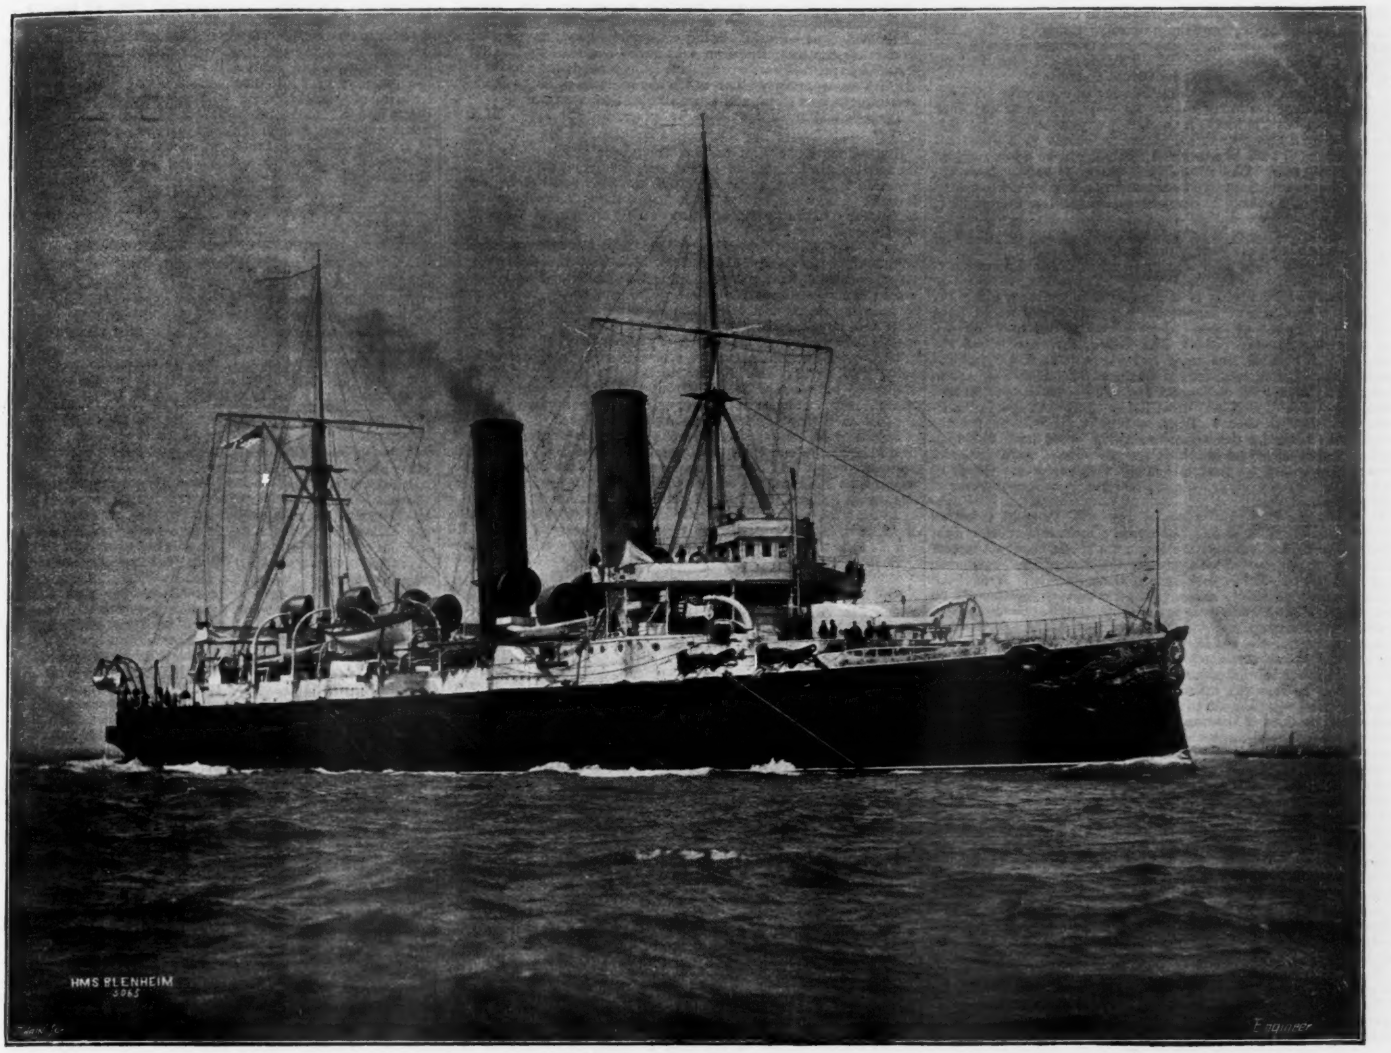
The average work of the Hone dredging machines per day was in 1893-94 as follows:—

| | Cubic metres. |
|---|---|
| Great dredging machine "Vaskapu" (Lobnitz) | 500 |
| Dredging machine "Halados" | 150 |
| Dredging machine "Kozla" | 150 |
| 1.—Crane excavator | 30 |
| 2.—Crane excavator | 100 |
| 1.—Priestman excavator | 10 |
| 2.—Priestman excavator | 10 |

Besides these engines and machinery the contractors employ, for the removing from rocks below the water, a tug of 500-horse power, another smaller one, a screw steamer, and for the purpose of transporting the Lobnitz, crushers, borers, and numerous boats. They put down nearly ten miles rails, of a length of more than 15 kiloms., on which six locomotives and more than 500 dumping cars are transporting the materials. Everything possible has been done to secure the completion of the works on the 31st December, 1895, as stipulated in the contract. And by this Hungary will fulfil a great mission, with which the powers have charged it by the Berlin Treaty of 1879. The navigation being assured at the cataracts of the Lower Danube, the gates of the Orient will be open not only for Hungary, but for the whole Occident.

A recently-issued report by Mr. Percy Sanderson, British Consul-General for Roumania, gives an interesting account of the improvements made in the navigation of the Lower Danube during the years 1878 to 1893 inclusive. The engineering works, which have been carried out under the able superintendence of Sir Charles Hartley, K.C.M.G., chief engineer to the Danube Commission, may be classed under three heads, viz., those on the Black Sea coast-line, those in the port of Sulina, and those in the river. The approaches to the port have been made safe by beacons, as well as by fog-signals and a "whistling" buoy, and the south pier at Sulina has been prolonged considerably. An even depth of 20½ft. has been maintained at the mouth of the river, and will be increased to 23½ft. by the completion next year of parallel dams. In the river numerous cuttings have been made, with the result that a minimum depth of 15ft. has been obtained on the whole of the Sulina branch of the river, while the course of the river has been shortened by six nautical miles.

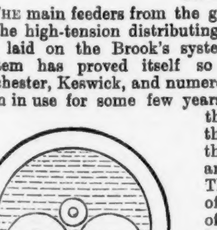
# HER MAJESTY'S PROTECTED CRUISER BLENHEIM



## H.M.S. BLENHEIM.

Her Majesty's ship Blenheim has been told off to bear the body of Sir J. Thompson, the late Premier of Canada, across the Atlantic. The Blenheim is in many respects a remarkable ship. She is a protected cruiser of 9000 tons, and is probably for her size the fastest warship in the world; the Blanco Encalada, for example, being much smaller. The Blenheim attained 22·5 knots under trial. She was launched in 1890; she was built by the Thames Ironworks Company, and her engines indicated 21,411-horse power, by Messrs. Humphrys, of Deptford. She is 375ft. long, 65ft. beam, and draws 25ft. 9in. She carries two 22-ton guns, ten 6in. guns, quick-firers, seven machine guns, besides small weapons. She can stow 1500 tons of coal; she has no side armour. Our engraving has been reproduced from a very excellent photograph of the ship, taken by Messrs. Symonds, marine photographers, Portsmouth. The Blenheim, which arrived at Spithead at midnight on Tuesday from Gibraltar, steamed into Portsmouth Harbour, and was berthed alongside the south railway jetty to await the body. The ship is to be painted black throughout, and a mortuary will be erected in the cabin, which will be draped. The remains are not expected to reach Portsmouth until Saturday. It is stated that the Admiralty propose to build four more ships of the Blake and Blenheim type, but much larger, and apparently to be slower, because the power is to be only 13,000 horses.

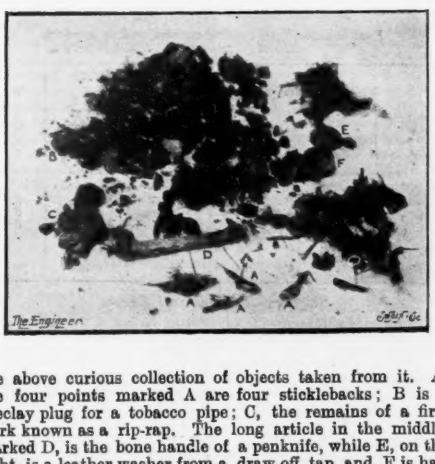
## HIGH TENSION FEEDERS, WORCESTER.



The main feeders from the generating station at Powick to the high-tension distributing sub-station at All Hallows are laid on the Brook's system of oil insulation, which system has proved itself so satisfactory at Chatham, Rochester, Keswick, and numerous other places where it has been in use for some few years. These feeders consist of three heavy wrought iron tubes, the metal having a mimimum thickness of ·25 of an inch, and an internal diameter of 2in. The conductors drawn into two of these tubes are made up of two $\frac{19}{14}$, and two pilot wires laid up together into one cable — the remaining tube being left spare. Special joint and junction boxes are placed at various points along the line, from which branch connections may be taken as required. Midway along the line an oil pressure tower has been erected, allowing for expansion and contraction—due to variations in temperature—of the thick heavy insulation oil. During the laying a very careful test was kept on the cable, and they were finally flashed with double the working pressure, namely, 5000 volts. The contract for the supply and laying of these feeders was given to Messrs. Johnson and Phillips, who are the sole makers of this system, which we do not doubt will now be more universally used.

## CURIOSITIES OF WATER SUPPLY.

We illustrate here an example of the curious nature of objects which, in spite of all precautions, make their way into the water supply of large towns. In a district which obtains its water from the Manchester Corporation, water was drawn for a special purpose from various street hydrants in different parts of the district, and had to pass through a rather finely perforated rose of about 4in. in diameter. The rose becoming choked, it was examined, and the above curious collection of objects taken from it. At the four points marked A are four sticklebacks; B is a fireclay plug for a tobacco pipe; C, the remains of a firework known as a rip-rap. The long article in the middle, marked D, is the bone handle of a penknife, while E, on the right, is a leather washer from a draw-off tap, and F is half of a walnut shell. It is easy to understand how these articles might chance to be found in the open filter-beds, but how they can make their way into the mains is somewhat of a puzzle, especially when the excellent quality of the Manchester water supply is considered. The conclusion is inevitable that these things must have found their way into the pipes or mains in the course of some repair or plumber's work, and probably in the neighbourhood in which they were found.



## TRIER'S "SPLIT-GRIP" COLLAR.

The split collar illustrated by the accompanying engravings is for shafting and axles of all kinds. It is made in halves, so that it can be taken off or put on without disturbing the shaft or spindle. It grips the shaft all round, and as it has no projections the danger to workmen of the ordinary collar with set-screw is obviated, and it will remain tight more certainly than with a set-screw, especially on shafts which are not true to gauge, or on which the ordinary collar is slack. By slightly recessing the shaft, the collar can be made to serve in place of a collar solid with the shaft, as shown by the engraving, Fig. 2. In this form the collar is capable of resisting thrust as effectively as if solid with the shaft. The two halves of the collar are united by the single cheese-headed screw T and the double right and left-handed screw S. The barrel-shaped head of the screw S is provided with tommyholes, lies wholly within a gap formed by the ends of the collar halves, and having the same radius as the raised central web, forms a practically unbroken continuation of the latter. The collar is fixed in place by first drawing the halves together with the screw S, a slight gap remaining; the screw T is then inserted and screwed tight; and lastly, the screw S is used to produce the tension and to cause the collar to firmly grip the shaft all round. The tension set up by the screw S imparts itself to screw T. The collars are made of toughened cast iron, turned bright all over, and although of light and elegant shape are very strong, the bursting tendency of the set-screw in ordinary collars being absent. Messrs. Trier Brothers, Westminster, have recently brought this useful invention before the public at a price which compare favourably with that of the ordinary collar.

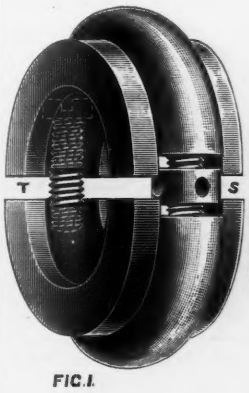


FIG. 1.

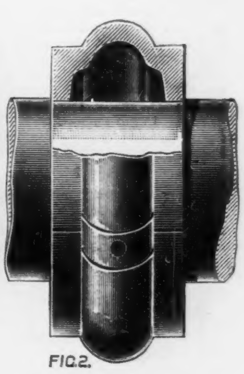

FIG. 2.

The deepening of the channel of the Port Adelaide River to a low water depth of 23ft., for a width of 250ft. from the semaphore anchorage to the port wharves, has been completed.

# LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

## LABOUR AND LUXURIES.

SIR,—The first I saw of the controversy in THE ENGINEER, upon "Labour and Luxuries," was the admirable letter by "Hirn," in your issue of November 2nd. Since then it seems to me that no attack has been made on "Y. X.'s" fundamental idea without making use of reasoning which he cannot understand.

"Y. X." seems to confuse the principles of economics with the principles of conservation of mass. He objects also to any time limit, unless I mistake him. He certainly objects to any moderate time limit, such as a year or so. Does he object to a time limit such as that of the life of a nation? This might be a few hundred or thousand years. The nation then ceases to exist. Does the money it has spent on foreign beer return to it after it has ceased to exist? Or if a nation, having spent much gold on foreign beer, is on the verge of bankruptcy—a not impossible case—is the money it has spent gradually coming back to it without any special effort to produce goods on the part of that nation?

The receivers of that gold are as well off as if it had been spent on iron or Bibles, according to "Y. X." The nation in question is worse off, so that what is commonly called mis-spending has produced a less sum of benefit than spending well would have done? Will somebody some day be better off to bring the balance straight? If so, who? The nation, the receivers of the gold, or the rest of the world? Perhaps "Y. X." objects to these limits. Let us consider the whole world. If three-quarters of the world spend all their gold for some years on beer, except what they must spend on bare living, will that gold "ultimately return" to them? Suppose it does, it will be greatly lessened in value, for three-quarters of the world have failed to replace their spades and other tools as they have worn out, and have not bought oil for their machinery, and so forth. Goods of all kind, including food, are scarce, and the purchasing power of gold is lessened.

Now, I hold that if this be true of nearly all the gold, it is true of any proportion that can be named; the value of the gold diminishing in proportion to the amount spent on beer rather than on tools or materials. This applies to the case of the shoemaker suggested by "Y. X." in your issue of December 7th. Even if the sovereign does ultimately return to the shoemaker, its value will be less than it might have been in some proportion to the number of shoes the shoemaker might have made had he bought leather instead of beer. For the fewer shoes made the dearer shoes will be, and the dearer therefore other things will be. According to the usual answer to workmen who want to raise wages and prices, it will soon be followed up all round. This will be seen more clearly if we go back again to a broader case. Put all the shoemakers in the place of the one, and let them spend, say, half their money for material, upon drink. But should this method of reasoning not be suited to "Y. X.," there is still another way of looking at the question. Suppose the sovereign to have been lost in a shipwreck in the publican's pocket.

Most men, "Y. X." among them, think there is some loss in the disappearance of the gold. Let "Y. X." admit further that in this case the sovereign—which the shoemaker had new from the Mint—has done less good to the community—represented by the shoemaker—than it would have done had it gone down at sea with the seller of leather. This being so, could the unexpected appearance of the publican or the seller of leather on a raft, sovereign in pocket, affect what the sovereign did, and the effect that it had while on shore? Surely not. Now is not the whole career of the sovereign made up of small transactions such as this? And does not the principle of integration hold as in mathematics? So that under a different series of circumstances—buying and selling—to any given series of circumstances, a sovereign will effect a different amount of benefit. To have no time test at all is equivalent to saying that the effect of certain atoms of gold during infinite ages will be good. In a dim kind of way "Y. X." seems to see this, but he does not see that the life of a nation, much more of a generation or less, is but a short event in the course of these ages, and that the effects of those atoms of gold collected into different masses may be good or ill in cases of different masses, during a generation or less.

Let us take "Y. X.'s" other case in which a man finds gold. Call this case 1. A. lives with unsatisfied desires. Coachbuilders live in want of employment. Horses are more numerous than purchasers. A. finds gold, orders horses and carriages, employing coachbuilders, who spend the gold in their turn. Now "Y. X." says that the whole community share the advantage. It is absurd to stop at such a statement. Let us analyse it. A. benefits by carriage and horses. The coachbuilder benefits by the profit on his work. His tailor and bootmaker benefit in the same way. Now I say that that lump of gold has done no more good than the same amount would have done had A. earned it—in the community.

It has enabled A. to get his carriage and horses without working for them. But let us take this case. Case 2: A. works as a consulting engineer, and earns the same value of gold as in Case 1, and spends it in the same way.

Now, the men who buy A.'s advice are not worse off for it; they have the advice—which is worth more to them, and through them to the community, than the gold they willingly exchanged for it. This I consider makes up for A.'s trouble in working, as against finding gold in Case 1. A. has his carriages and horses. The coachbuilders, and the community through them, are in the same position as before. In both cases the community finds horses rather dearer. In my case—Case 2—it finds good advice rather cheaper, for an increase in any commodity tends to make it cheaper. Cheap bread, clothing, and good advice are an advantage to the community—always in pure "Y. X." economics, usually in ethical economics.

"Y. X." says labour can be wasted, gold cannot. I consider that gold is being wasted if it causes labour to be wasted. If I spend three years making castles in the sand, there is a loss to the community—even if I become sane and diligent at the end of the three years. On the whole, Sir, the mistake made by your reader "Y. X." is, that he is always dealing with gold, while he should think as well of men and their work.

R.

December 19th.

SIR,—I am much obliged to "W. A. S. B." for supplying me with a definition I lacked. Smith says, "the sole use of money is to circulate consumable goods." That is precisely what I have contended for all along. So far as gold is concerned it matters not a whit what the goods are. When a man has received a sovereign he has received all the potentialities of that sovereign. The gold can do no more for him. It matters not whether it was got honestly or not. The gold represents so much power. But the quantity of gold in any country is limited. If one man has it another man must go without. Peabody's buildings were built not only at Peabody's expense, but at that of some other body of individuals, not builders, who would have received his money if he had not been charitably disposed. The passages quoted by your correspondent really have nothing to do with my contention. But they admit of being traversed. I do not know whether "W. A. S. B." has ever read a little book, by an author whose name I forget, showing that although thrift was the best thing possible for the individual, it is the worst for the nation. Thus, one man spends his sovereign on boots, let us say, while another invests it abroad, and goes with worn-out boots from motives of economy and thrift. It is quite evident that the former gives more employment than the latter at home, and so far is a better friend to his country.

Mr. Phipson falls into an amusing error. The quantity of land available for purchase is a constant quantity, and it matters nothing to the wealth of the community who has it so long as it is used. If a man sells land and gets gold for it, it is to be presumed that he will spend the gold—distribute it, that is, to circulate consumable goods. We have on the one hand land, on the other gold. A has the former, B the latter. They exchange. I cannot see that this alters the position of affairs in any way.

If a man sells land or anything else, and sends the gold out of the country, while he gets bonds in return, then the country losing the gold is the worse of the transaction; the potentialities of the instrument for circulating consumable goods are transferred to another country. But even that is not necessarily a loss, for it is well-known that vast works have been carried out abroad with English money, nearly all of which has come back to us for rails and engines, and ships, and engineers, and contractors.

December 17th. Y. X.

SIR,—The view that I set out to enforce is that it is highly inexpedient, in treating of labour questions, to put forward debateable theorems of abstract political economy; and that the case is made worse when, as usually happens, these theorems prove to be contrary to the opinions of the great writers upon whom they are fathered.

As to the original question, I hold that Government employ ought to be as steady as possible, and that the discharge of labourers during winter suggests mismanagement. But I see no reason to suppose that the economic position would be improved by reducing the salaries of clerks. Probably "Y. X." would agree with this much, which is not abstract economy, nor for that matter is it ethics, but a question of statecraft.

This was the original question, soon shifted to an obscure debate as to gold, as to which I wish to add that on pages 50-52 of Mahan's "Influence of Sea Power upon History," there is a lucid account of the collapse of Spanish and Portuguese commerce, consequent on their discovery of the American mines.

Finally, "M." asks for practical remedies for depressed trade, or do I misrepresent him? Will he kindly read Mr. John Inglis's address on page 368 of your number for October 26th, and say whether he finds that an accurate outline of the present position, or in what he finds it deficient? If we can come to an agreement as to the past, we shall better our chance of profitably discussing the future, though we can hardly expect that abstract science will point out to us safe 5 per cent. investments. W. A. S. B.

December 17th.

SIR,—It would be interesting if "W. A. S. B.," or some other of your correspondents, would say something concerning the rate at which gold circulates, and the influence of that rate upon the prosperity of a country. In a certain community there is one sovereign, which passes from hand to hand, and serves as the medium of trade. The man who has not got the sovereign cannot buy. There are, let us say, 100 persons in the community. The sovereign circulates at a certain speed, and answers every purpose. The colony now receives an addition of 100 individuals, but no more money. It appears to me that the single sovereign can still do the work of the colony, provided it circulates twice as fast as it did before. It would appear therefore that the trading power of a nation depends not so much on the quantity of the circulating medium which it possesses, as on the rate at which that changes hands. How, in practice, is the rate fixed? I cannot call to mind any discussion of this question in your columns, or indeed elsewhere. ALAN STEWARD.

Bath-street, Glasgow, December 19th.

## THE MACHINERY OF SHIPS OF WAR.

SIR,—In the article headed "The Machinery of Warships," appearing in your impression of the 14th inst., reference is made to the omission of explanations respecting the reasons which have induced the Admiralty to adopt the Belleville boiler so extensively. These reasons are known to many, but perhaps the following information may be of service to those who are sceptical as to the advantages and capabilities of this system of water-tube boiler:—In order to ascertain the comparative evaporative efficiency between the ordinary cylindrical single-ended boiler and boilers of the Belleville type, the following trials were made:—A vessel with cylindrical single-ended three-furnace boilers was selected. Two of these boilers worked in battery were used, the total grate surface being 138 square feet, and the total heating surface 3880 square feet. A group of four Belleville boilers, having a total grate surface of 135 square feet and heating surface 3842 square feet, was then selected for experiment. It will be observed that as regards grate and heating surface the boilers above mentioned are practically identical, the cylindrical with the water-tube.

Trials were made in order to ascertain how many pounds of water could be converted into dry steam per pound of coal, burning the same with natural draught and at approximately equal rates of combustion. The vessels were moored alongside the quay, and water was taken from the town main and measured carefully into tanks before being pumped into the boilers. The trials were made at the same place, by the same staff, with the same quality coal, and under as nearly as possible the same conditions, in order to render the comparative trials perfectly fair. The following particulars give the results:—

*Belleville Boilers—Evaporative Trials.*

Four boilers—Total heating surface, 3842 square feet.
Total grate surface, 135 square feet.

| Duration of trial. | Coal consumed in lb. per sq. ft. of grate. | Water evaporated per lb. of coal from temp. of feed. | Steam pressure in boilers. | Temperature of feed water, deg. Fah. | Quality of coal. |
|---|---|---|---|---|---|
| 8 hours | 18·8 | 8·3 | 200 lb. | 40 deg. | B'st Welsh |
| do. | 19·43 | 9·1 | do. | 40 deg. | do. |
| do. | 19·4 | 9·0 | do. | 40 deg. | do. |
| do. | 24·5 | 7·83 | do. | 50 deg. | do. |
| do. | 12·0 | 8·5 | do. | 50 deg. | do. |
| do. | 12·0 | 9·16 | do. | 50 deg. | do. |
| do. | 9·2 | 8·64 | do. | 50 deg. | do. |

*Single-ended Cylindrical Boilers.*

Grate surface, 138 square feet. Heating surface, 3880 square feet.

| | | | | | |
|---|---|---|---|---|---|
| 8 hours | 12 | 7·59 | 124 lb. | 50 deg. | B'st Welsh |
| do. | 20 | 8·02 | 124 lb. | 50 deg. | do. |
| do. | 28 | 7·85 | 138 lb. | 50 deg. | do. |
| do. | 12 | 8·44 | 110 lb. | 50 deg. | do. |
| do. | 20 | 8·09 | 110 lb. | 50 deg. | do. |
| do. | 28 | 7·86 | 132 lb. | 50 deg. | do. |

It should be noted that the above results were obtained from feed-water, and that the water-tube boiler raised steam to 200 lb. pressure, against the cylindrical boiler at from 110 lb. to 138 lb. This was necessary in order to make the comparative tests perfectly fair, because although in the Belleville boiler steam was raised to 200 lb. per square inch, it was reduced to 135 lb. per square inch at the engines; whereas, in the cylindrical single-ended boilers the engines were supplied direct from the boiler at the working pressure. In all the trials the water-tube boilers had very much the best of the battle. Moreover, owing to the reduction of pressure between the boilers and engines, the steam was delivered to the engines in a superheated condition in the case of the Belleville, and was consequently plus this advantage.

Now the question of weights. The cylindrical boilers were to Admiralty scantlings, and weighed, together with water, lagging, fittings, and uptakes complete, about 100 tons. The Belleville boilers weighed, with casings, brickwork, fittings, water, and all appurtenances peculiar to this system, about 50 tons, showing a saving of, say, 50 tons in favour of the water-tube boiler.

Having so dealt with the important questions of evaporation and weight, there is still another feature which, in the opinion of those who thoroughly understand the system, places the Belleville boiler before other water-tube boilers as a serious sea-going steam generator. We allude to the fact of the boiler being composed of separate elements, all interchangeable and readily accessible, which enables the engineers to examine and clean all heating surfaces with the greatest facility, thereby ensuring that the boiler maintains its original efficiency. Should a tube leak at sea it is the work of a few minutes to remove the element containing the damaged tube, and replace it by a spare one. In short, whereas the majority of water-tube boilers in the market retain certain features of the water-tank boilers, inasmuch as they have tube-plates and tubes expanding therein, the Belleville boiler consists of tubes pure and simple, and may be considered rather in the light of a high-class and ingenious mechanical contrivance for the generation of steam than a boiler in the generally accepted sense of the word.

(For Maudslay, Sons, and Field, Limited)
London, December 18th. JOHN SAMPSON, Director.

## THEORY OF THE STEAM ENGINE.

SIR,—Mr. Cherry has a vivid imagination. Nothing short of a vivid imagination could connect—as he has done—Carnot's theorem with a "faked brake." Mr. Cherry must pardon me if I say that he deceives himself if he fancies that Carnot's theorem has ever enabled him to prove that an inventor of a steam or other heat engine, was wrong. I am not surprised, however, that he should imagine such things, seeing that he takes the trouble to assure your readers that he never asserted, that because the three angles of a triangle are equal to two right angles, therefore the efficiency of a heat engine cannot exceed $\frac{T - t}{T}$. If Mr. Cherry will read my letter with care half a dozen times, perhaps he will understand it. Here I take leave of Mr. Cherry.

I am much obliged to Professor Alexander for correcting the statement in my last letter. I fear that hurry and indifferent eyesight must plead my excuse. The temperature of 150 lb. steam is 358·3 deg. Fah. But in reality it matters very little whether the efficiency of the steam engine is or is not greatly in excess of that of a Carnot engine working within the same limits of temperature. If it be equal to the latter that is enough for my contention, because the steam engine does not comply with Carnot's conditions. It is not reversible; it does not work on a closed cycle; it does not take all its heat at the same temperature; and yet it equals the efficiency of the Carnot system.

It is worth while, however, to push the inquiry a little further, and for this purpose I shall use figures given in D. K. Clark's "Rules, Tables, and Memoranda." I take an engine working with steam of 100 lb. pressure, with an eight-fold expansion, and 7 per cent. clearance. The terminal pressure is 12·5 lb. Such an engine, calculating the heat in the steam from 102 deg. Fah., which may be taken as that of the feed-water, utilises 18·6 per cent.

Now the initial temperature in the cylinder is 328 deg. The terminal temperature is 204 deg. omitting fractions, and the efficiency fraction $\frac{T - t}{T}$ is 15·7. Rankine, page 410 of the "Steam Engine and other Prime Movers," gives the efficiency of an engine using 100 lb. steam, expanded 10-fold, and allowing 4 lb. back pressure, as ·177 per cent.; calculated by temperatures its efficiency is 17·1 per cent.

I must now turn to Professor Alexander's observation about isothermal and adiabatic expansion. So far as I can ascertain, no one has ever yet calculated with any certainty the adiabatic curve for steam. I do not believe it can be so calculated. There are three different constants in use for the purpose, which is right no one knows. There is $pv^{\frac{10}{9}}$ and $pv^{\frac{17}{16}}$, and one other used in the United States which I forget. Under the circumstances I have used, as all engineers do, the ordinary hyp. log. method, which, so far as I know, very nearly coincides with practice. The difference between the adiabatic and isothermal is very small. The 7 per cent. clearance given by Clark is against economy. But further, I need scarcely tell Professor Alexander that by the addition of a very small additional quantity of heat for superheating the steam a few degrees, I can much augment the efficiency of an engine, in practice going a long way to keep up the expansion curve to the isothermal line. Furthermore, I would remark that if we raise the temperature of the feed-water to that of the steam, which can easily be done by the waste heat, the efficiency of the engine will much exceed 18·6 per cent. Thus, if the feed went in at 212 deg. the proportion of the heat supplied to the water in the boiler utilised by the engine would be 20·7 per cent.

Perhaps Professor Alexander will pardon me if I ask him to give me some information on a question which puzzles me much, and concerning which I can obtain nothing directly to the point from Maxwell, Cotterill, Isherwood, or, indeed, any other writer on thermodynamics. Of course it is possible that my question is not susceptible of being answered, but nevertheless I put it. To make its bearing quite clear I must suppose a case.

In a long cylinder I place one pound of water, and on top of that a piston with 144 square inches of area, loaded with 21,600 lb.—that is to say, 150 lb. on the square inch, including the atmosphere. The cylinder walls, &c., are non-conducting, the water at 32 deg. Fah. I apply heat, and I pour into the water 358 B T U. No external work whatever is done by this heat; only the temperature of the water is raised. When 358 deg. have been slightly exceeded the piston will rise. When it has risen 3ft. all the water will have disappeared, and we shall have one pound of steam at 150 lb. pressure and 358 deg. temperature. The work done will have been 64,800 foot-pounds, and the thermal units spent 861·5. Is this latter figure correct? It seems to me that it is not. The specific heat of saturated steam is ·305, that of water being 1. The water required 358 units to raise its temperature to 358 deg., but the steam cannot require more than 358 × ·305 = 109·19 units, say, in round numbers, 109 units, to maintain its temperature. Is not the difference between this and 358—that is say 249 units, set free, either to augment what is called the latent heat of the steam, or if it does not do this, then to reduce the number of units required from the fire to convert the water into steam?

"It may be noted," says D. K. Clark, "that ·305 is the quantity by which the total heat of saturated steam is increased for each degree of temperature." If it is urged that this only applies to steam already made and not to steam in process of formation, I cite the following further passage from Clark: "The expression ·305 for specific heat is taken in a compound sense, comprising the changes both of volume and of pressure, *which take place in the production* of saturated steam." The italics are mine. Turning now to Maxwell, page 171, we have the following suggestive passage: "A third mode of defining specific heat is sometimes adopted in the case of saturated steam. In this case the steam is supposed to remain at the point of saturation as the temperature rises. It appears from the experiments of M. Regnault that heat leaves the saturated steam as its temperature rises, so that its specific heat is *negative*, a result pointed out by Clausius and Rankine."

I am not sure how far this latter statement bears on my question. I take it for granted that the steam in this case is supposed to be in process of formation, the pressure gradually rising in the boiler. But I do not quite see why if the specific heat, be it what it may, is constant, any heat should be given up by the steam simply because its temperature rises.

However, it seems to me, that whereas 358 units would be needed to maintain the temperature of a pound of water under 150 lb. to the inch pressure at 358 deg., only 109 units are required to keep a pound of steam at the same temperature, the pressure being 150 lb.; and I want to know, if this is the case, what becomes of the 249 units difference, representing as they do 192,228 foot-pounds

The most intelligible way in which the question can be answered would be, I think, to give a table of steam pressures, &c., in a way something like the following. Perhaps Professor Alexander will do this:—

| Total pressure. lb. | Temperature. Fah. | Units per lb. of steam. | Units latent. | Total units per lb. of steam. |
|---|---|---|---|---|
| 150 | 358 | 192 | 999 | 1191 |

At the risk of making this letter too long, I must seek a little further information. If one pound of steam of 150 lb. is expanded fifteen-fold, it will occupy 45 cubic feet very nearly; what will be its terminal temperature, supposing that it has expanded in a non-conducting cylinder behind a piston? Will the pressure be that proper to that temperature, whatever it is, as set forth in steam tables? Let me, for the sake of argument, assume that the terminal pressure will be 10 lb. Now, in the steam tables the temperature for this is 193·3 Fah. Will that of the expanded steam be more or less than this? At first sight it would appear that it must be less, but this is not quite clear. A pound of steam at 10 lb. pressure will fill a space of only 37·84 cubic feet; but a pound of 150 lb. steam expanded fifteen-fold will fill—ostensibly—a volume of 45 cubic feet, nearly. The total heat units in the high-pressure steam are 50 in excess of those in the low-pressure steam. Now, if the steam expanded without doing work, these 50 units would go to superheat it, I presume, as Rankine suggests, but as the steam is supposed to do work, will not these 50 units tend to keep up the expansion line of the diagram? Will not they be converted into work before liquefaction takes place? and will not the terminal pressure be something near 10 lb.?

One question more and I have done. The specific heat of water being greater than that of steam, then every ounce of water produced in a cylinder, either by the performance of work or otherwise, must rob a further portion of steam of its heat, because the water will be at the same temperature as the steam; but it requires much more heat to keep an ounce of water at a given temperature than an ounce of steam. To reverse Regnault's proposition: when the pressure of steam falls it must part with heat to any water present, in order that the latter may maintain its temperature.

Finally, it is quite likely that Mr. Cherry and others may tell me to go and look in my books for an answer to my questions. My reply is that I have looked—in Maxwell, Rankine, Isherwood, and several other authors—and that I can find no definite reply; if I could I should not trouble Professor Alexander. Indeed it appears to me that possibly because of the great difficulty of carrying out experiments with steam, very little more is known about it than is set forth in the ordinary steam tables. I can see that very great difficulties must be encountered in any attempt to ascertain how many units of heat have been converted to maintain the temperature of a pound of steam. Such diagrams as that given by Clerk-Maxwell on page 135 of his book, are very good in their way; but they seem to me to be just a little make-believe, and after all they tell us next to nothing concerning the way in which heat is distributed. With air, and gas generally, the matter is quite different. Perhaps Professor Alexander can settle the whole question in a few words, by referring me to some paper or treatise in which the answer to my question is set forth. MAURICE CROSS.

December 17th.

Sir,—It appears that Carnot's argument is based on the assumption that no matter what the nature of the working fluid, the capacity of the fluid for performing external work will always vary exactly as the temperature. Now, taking Maxwell's proof, as quoted by Mr. Cross in your last impression, the following suggests itself: Let us take two heat engines working with different fluids within the same limits of temperature. Then, if the fluid in one is more efficient, in the sense that it has a greater capacity for doing external work than the fluid in the other engine, then this last can drive in a reverse direction the first engine, and such driving would, I think, be in no way inconsistent with experience. But it would quite demolish Maxwell's proof.

Unless it can be proved that the capacity for doing external work varies in all cases as the temperature, then the whole proposition breaks down. Because, let us have a reversible Carnot engine working, say, with air within certain limits of temperature, T and *t*. This is by Carnot's theorem the most economical engine it is possible to construct. But if a second engine working, say, with ether or chloroform, can within the same limits of temperature do more external work, then it would be more efficient than the most efficient engine; but this is impossible. Therefore the air engine, although complying with Carnot's condition, is not the most economical that it is possible to construct. X.

Brixton, December 14th.

## PROPOSED ASSOCIATION OF PORTLAND CEMENT MANUFACTURERS.

Sir,—In reference to the attempt made by Messrs. Knight, Bevan, and Sturge to form an "Association of English Cement Manufacturers," we should like to call the attention of all interested in the matter to some points which may have been obscured or may have escaped notice. Any firm which joined that Association would practically have declared that it never had and never would make any improvement in the manufacture of Portland cement. Of course, those who were willing to pledge themselves never to advance sought to cast a stigma on the progressives by substituting the word "adulteration" for improvement; but this little interested move was quickly exposed by several speakers at the Cannon-street meeting. In the circular issued to convene this meeting, it was stated that the admixture of ragstone and other inert materials with Portland cement was "bringing disrepute upon the good name that English cement has hitherto borne in comparison for quality with cement of foreign manufacture." Now, in reference to this point, *Fairplay*, in an article on cement in its issue of November 30th, pathetically remarks, "It is ridiculous to suppose that with the purest chalk and purest clay the English possess they cannot make better cement than the Germans, who have none such." In the *Brickbuilder*, a journal published in Boston, articles on cements and cement tests have recently appeared, in which two classifications of cement were made:—(1) German cements of first quality; (2) English cements, generally bracketed with Belgian cements, as of second quality. "This is a serious matter for the commerce of this country, and is well entitled to the attention of engineers, who should show how thoroughly unfounded is such a supposition."

Casually remarking that *Fairplay* and Mr. Bevan appear to be remarkably unanimous, their contention scarcely looks as though the quality of English cement bore such a high character as Mr. Bevan assumed. The policy they propose for the reinstatement of English cement is so remarkably guileless and childlike as to deserve special notice. We are not to make any endeavour to improve our cement, not to compete with German skill, but to fold our hands and say, "Our cement is made of chalk and clay—as it has been since the Flood—and nothing else. If foreign cement gives better tests, we can't help it; it only proves that it is adulterated."

Mr. Leedham White, however, fully recognised the necessity for English manufacturers not thus sitting with folded hands while foreign competitors are working, when, at the Cannon-street meeting, he said that English cements had not recently been brought into disrepute in comparison with foreign cements, seeing that English manufacturers were actually exporting even better cement than they did a few years ago. "But," said Mr. White, "we have been distanced by German skill and German competition, which is a different thing. I am most anxious that we should not be debarred from imitating the German skill. We do not want to be debarred, as people who intend to make progress in every shape and way, from taking advantage of scientific research."

It must be remembered that the various tests were not invented in the interests of the manufacturer, but in those of the consumer. The engineers and chemists who invented the tests invented them to compel the manufacturer to improve his cement. It is therefore rather illogical, when a manufacturer improves his cement to meet the higher specifications, to throw doubt upon the efficacy of the tests. English manufacturers would, if this were accepted, be placed in the position of having foreign cements preferred to theirs because they passed higher tests, and at the same time they would be forbidden to so improve their manufactures as to make it meet these higher tests. But, as Mr. White pointed out, when a manufacturer supplies cement which meets all provided tests and analyses, he has fulfilled his legal obligations, and when he goes beyond this and supplies cement, which, besides meeting all tests, will give enduring satisfaction he has fulfilled his whole moral duty.

Now, leaving the general aspects of the question, we should like to point out that at the Cannon-street meeting Mr. Holt, on our behalf, frankly owned that we had improved our cement by the addition to it of Kentish ragstone of a special quality and in a carefully considered proportion. He strongly deprecated such an addition to the cement being stigmatised as an adulteration, and courted the fullest inquiry into the improved manufacture. A subsequent highly influential meeting of the cement trade at the London Chamber of Commerce has acceded to his request by the appointment of a committee having power to call in expert evidence in reference to the addition of Kentish ragstone in the manufacture of Portland cement.

At the Cannon-street meeting Mr. Holt, in spite of an attempt which was made to prevent his giving the information, brought out the fact that his manufacture improved the cement in colour, in tensile strength, and in the sand tests. They were:—At seven days, 492 lb.; at three weeks, 556 lb.; at seven weeks, 656 lb.; at three months, 740 lb.; at six months, 790 lb; at nine months, 975 lb.; at eleven months, 1000 lb.; and at twelve months, 1010 lb. With sand tests—three and one—nine months gave 410 lb. in one case, and 460 lb. in another. In reference to these tests, we should like to call especial attention to the excellence of the long-time tests.

The long-time test, when three parts of sand were added to the cement, is most important, as no cement of indifferent quality could give such high results when mixed with these proportions of an inert matter such as sand. This shows that our improved cement in the neat state must contain less inert matter than the old-fashioned cement, because if it were no better than the old cement it would, when mixed with three parts of sand, be bound to give a worse result for tensile strain when tested. Since the Cannon-street meeting our tests have been witnessed by other cement manufacturers; and we cordially invite any manufacturers, engineers, or customers to come down to our works and judge the tests for themselves.

It must be borne in mind that Portland cement is only the name for an article of admixture, which, if it satisfies the provided standard tests and chemical analyses, and, in addition, the tests of time and exposure in actual use, cannot be said, with the least show of reason, to be adulterated because there may happen to enter into its composition an ingredient or ingredients whose beneficial action has only lately been discovered. Still less justifiably can it be called adulterated when it gives results under all tests far beyond anything hitherto demanded in any specification. In a previous part of this letter are mentioned the high results which the new cement has given under all conditions. Its principal points are its improved colour and its very markedly improved results in the long-time tests, especially noticeable when the cement is mixed with sand.

In conclusion, we would remark that we should hardly be guilty of such a suicidal business policy as to place on the market a cement which we had not put to the severest tests. Our improved production has come out triumphantly, not only from all the provided scientific tests, but it has been used in work which has borne the more solid and satisfactory tests of time and exposure to varying temperatures, including the severe cold of last winter. In addition, so far from having had the slightest complaints about it, we have received nothing but the highest commendation of its unchangeable qualities. MACEVOY AND HOLT.

Britannia Cement Works, Northfleet, Kent, December 17th.

## TRACTION ENGINES.

Sir,—The letter of your correspondent "J. H. M." deals with the traction question in a full and comprehensive manner. Unless I am much mistaken in the identity of "J. H. M.," his letter carries much weight, coming from one with large experience in such matters. With regard to engines appearing before a licensing committee, it would result in little improvement unless the committee were technically advised. Such bodies—as Corporation Building Committees and the like—are often composed of men ignorant in the matters at issue, and their knowledge of steam engines is about as comprehensive as that of the driver so often quoted. Even if the committee were technically advised I am afraid much scamped work would be done. Proprietors repairing for inspection only would leave their engines for the rest of the year in the present usual state. What is wanted are inspectors engaged by the municipal and district council authorities. The owner's licence would then depend upon their report as to the condition of the engines. I am of the opinion that some such course would be the only means to keep owners and drivers attentive to their charges. I have seen engines come in for repairs when almost past such treatment, their bad state being due to only a few months' work and gross negligence, whereas a clean up every week would have prolonged their existence considerably. Cannot owners see it is against their best interests to allow such a state of affairs? There is a firm that allows "muck money" to men engaged on such repair work, to enable them to meet their increased washing bill, and shovels are constantly used to remove the accumulated dirt from fire-box sides.

I can fully endorse "J. H. M.'s" remarks on "rack steerage," having known accidents due to breakage of chains. As to compounding, I am somewhat surprised to learn that its theoretical value disappears, and should be still more so if Mr. Gakee informed us that its practical value also disappeared. "J. H. M." could, no doubt, give us some interesting results on the matter. Will he do so?

Prescot, December 15th. VIARY.

Sir,—The excellent leaders and ample correspondence lately published in your columns have so well discussed the *pros* and *cons* of this subject, that one feels any further contribution may appear like "carrying coals to Newcastle."

In your issue of the 7th inst. "J. H. M." writes with much authority and displays some knowledge of the subject, but his suggestions remind one of the old danger of "jumping out of the fry-pan into the fire." Had he had much experience in the working of traction engines he would have hesitated, I think, to make such complicated and bewildering proposals. He says it is "against progress to prohibit," and yet suggests regulations which, to my mind, are practically prohibitive. His definition of "the best engine," and his recommendations—in the last paragraph of his letter—are very well in their way; but he may be assured that what is best will always come to the front and claim adoption.

After a long experience amongst ploughing engines, agricultural and road engines of all types, I feel certain it would be for the good of the nation at large if most of the existing legal regulations—and all the bye-laws—by which such engines are now surrounded were abolished; and I would suggest that both the engines and the traffic should be permitted a free growth. The inexorable laws of "natural selection" and "the survival of the fittest" surely apply to this matter as to everything else. You may depend upon it, if engine owners, steam hauliers, engine builders, and the public—not excepting road authorities—were allowed a free hand, it would be found that they are all well able to take care of themselves; and further, such a course would of necessity tend to develope a perfect road engine or steam carriage, such as would meet the varied requirements of users, and arrangements for working traffic would naturally adjust themselves. Such freedom would at the present moment be a great boon to agriculturists, who are in such urgent need of facilities for cheap and speedy transport.

If, however, public opinion—to which, rightly or wrongly, we must all bow—demands strict statutory regulations for road engines, a thorough revision and amendment of the existing road locomotive Acts is imperative, and should be made at once, such revision and amendment to be dealt with by a competent Parliamentary Committee or Commission. The amended enactments, in my opinion, should embody or provide for the following:—(1) One licence—to cover Great Britain—granted by one central authority. (2) Uniformity as to the hours engines may travel. (3) Granting certificates to engine drivers. (4) All bridges, main and turnpike roads to be constructed for traction engine traffic, which should be considered as ordinary and necessary traffic. In the present state of British industries and agriculture, it is needless to argue the necessity of the road engine. "It has come to stay," as one of your correspondents pithily remarks. Those who would hamper or unduly restrict such engines, or raise paltry objections to their use, can only be classed among those who "have eyes and see not." Any obstructive or restrictive policy will, in the long run, have to make way for necessary progress. J. A. C. B.

December 17th.

Sir,—I have read your articles and the correspondence on the above subject. I would like to speak on the subject from a practical point of view. I have been driving road engines for a great number of years, and have removed thousands of tons of boilers and other heavy pieces of machinery, as well as done ordinary road travelling over thousands of miles. I am a practical mechanic, and do not let my engine get into the disgraceful condition spoken of in your article and correspondence. If road roller practice is the satisfactory state an engine should be in, I keep all in condition equal to the best of them. I have used cross-bar wheels, both rigid and spring spokes, and can say, with a heavy load on slippery roads and pavement they are a real nuisance, annoying to a driver as well as trying to the temper of any ordinary mortal, to say nothing of the damage the diagonal strips do to the road. It has been my privilege to drive engines both simple and compound, fitted with many different kinds of wheels, india-rubber tires, spring spokes and spring block wheels, as well as the wood block wheels. The india-rubber is a wonderful wheel, but the chain armour is a great trouble to keep in order. The next best wheel I consider the wood block wheel, which can travel where and when the cross-bar wheel is useless.

Your correspondent, "J. H. M.," knows these wheels and says they are too heavy for ordinary macadam; this in practice I have not found to be so. Such a large surface of wood blocks is presented to the road that there is little pressure on the square inch of road, and if these wheels are kept in order they will satisfy both owners, drivers, and road authorities. I am surprised that the use of something of this sort is not made compulsory. If neglected, any kind of driving-wheel is unfit to go on the road. The advantage of the wood block wheel is that the blocks adapt themselves to the inequalities of the road, while the ordinary wheels of equal diameter back and front, running on hard round-topped roads, the wheels only tread on a very few inches of the inner edges, thus forming a knife edge that cuts through macadam and chips and breaks sets, and is a prime cause of breaking axles. Any wheelwright used to setting heavy road wheels would laugh at the ordinary engine wheels. For the ordinary cross-bar wheel to get a proper bearing, the hard road would have to be made specially to suit it, billiard table fashion.

I should like to see the law so altered that one licence would allow an engine on any road in the kingdom at any time, and no restrictions whatever but those in the Imperial Act. At present hours are wasted to meet local bye-laws, as though men's time and engine's delay were not of the slightest consideration. I am often compelled to be working two days to do one day's work.

Manchester, December 18th. JAMES LOCKWOOD.

Sir,—The valuable and interesting correspondence in which you are taking such a kindly interest is of the greatest importance to engineers and others. The valuable suggestions as to the modification of the present Act of Parliament and local bye-laws are pretty sure to have some good result.

I notice the various suggestions by various men who I know have had considerable experience, but I am afraid that some of them lose sight of the fact that what we really want is a road locomotive for hauling road traffic only. The traction engine in its present form has done very good work as a general servant. We know pretty well how it had its origin. It would be quite as consistent for any of our large farmers to attempt to use one of their nearly thoroughbred hackney or carriage horses for a wagon horse or for ploughing as it is to use the traction engine with its cross-bar wheels for road hauling. Seven years ago I took out a patent for an improved traction engine and traction engine wheel. This was the result of forty years' practical experience with steam on common roads. I propose to put my engine, as I have done many a one, on three wheels. This at once overcomes the danger that one of your correspondents suggests might happen at high speeds to an engine with two leading wheels steered by a chain. In my arrangement the whole of the working parts are out of sight. I do away with the multiplicity of gearing. The engine altogether is as effectually and freely on springs as a railway locomotive. I have travelled many hundreds of miles by steam on common roads with three-wheeled engines, and never had the slightest difficulty in steering. It is much quicker and easier than with four wheels.

Then as to boilers in the present locomotive boiler form, we know that it is a daily occurrence on common roads that an engine going down a steep hill dare not stop because the surface of the water has left the fire-box top bare, the water having gone to the lowest part of the boiler at the chimney end, and the man must either pull out his fire or move at once or drop his lead plug.

What the road locomotive wants is an improved simple vertical multitubular boiler with horizontal tubes. The engine embodying these rough suggestions can be hung efficiently on springs, everything completely boxed in and out of sight, and the outward appearance as snug and sightly as any conveyance we meet on the road to-day. I. W. B.

Ashton-under-Lyne, December 18th.

## RADIAL DRILL TABLES.

Sir,—In the excellent description of the Atlas Locomotive Works in your issue of the 14th inst., reference is made to the turnabout table attached to the radial drill in the boiler shop as if it were a novelty. This table was one of the many inventions of my father, the late Mr. George Crow, who was works manager here for many years, and who had the first table made at these works and put in use as far back as 1869. The demand for these by the same makers still continues. At the latter part of 1869 my father made an arrangement with Messrs. Fairbairn, Kennedy, and Naylor, Leeds, by which for a term of years they had the sole right to make and sell them, and they supplied both private firms and railway companies with them under that agreement. We have six of these tables in use at our locomotive shops and at our marine boiler works at Hebburn-on-Tyne, and I am surprised that they have not come into even more extensive use for general work.

Newcastle-upon-Tyne, W. H. CROW.
December 17th.

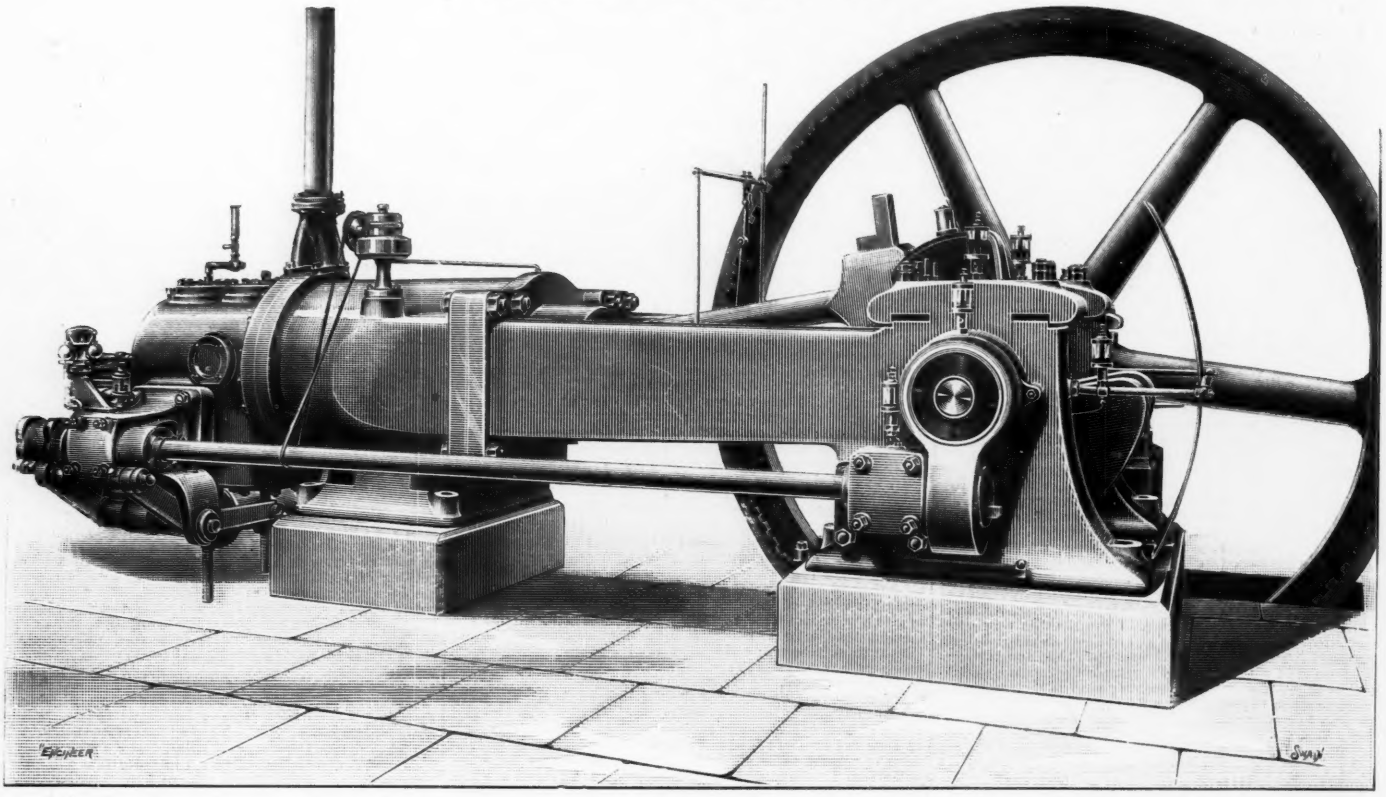
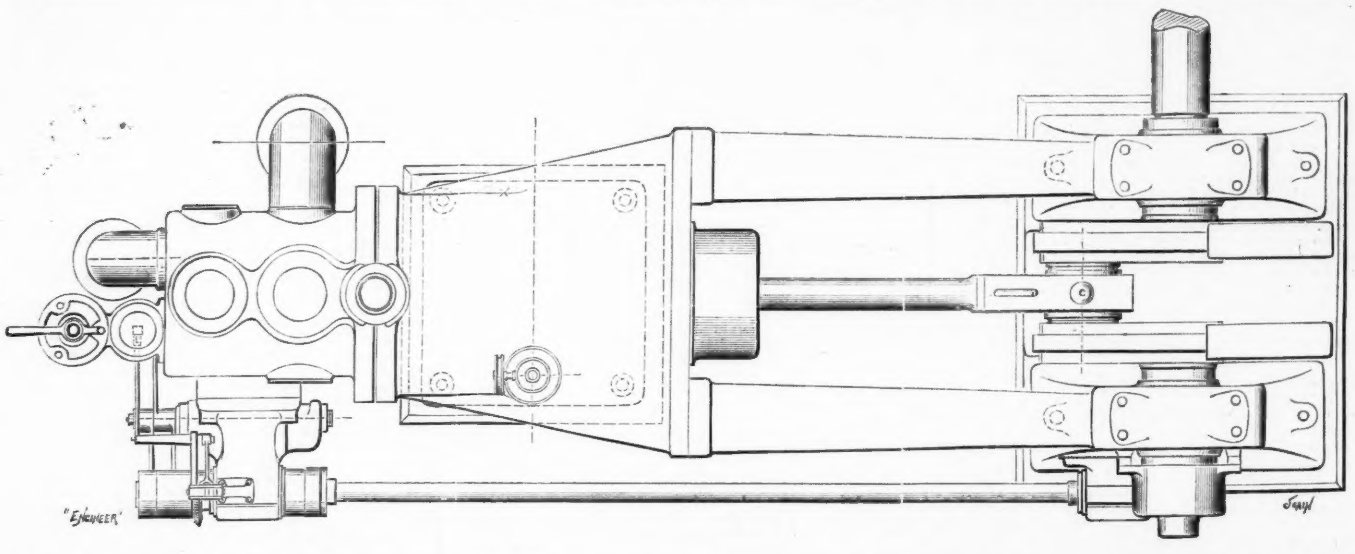
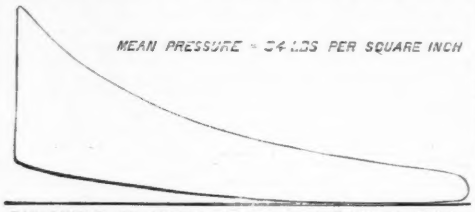
# ONE HUNDRED-HORSE POWER GAS ENGINE

MESSRS. ROBEY AND CO., LINCOLN, ENGINEERS

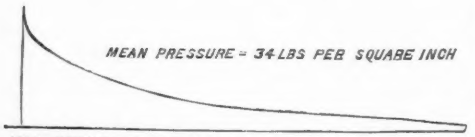


## 100-HORSE POWER ROBEY GAS ENGINF.

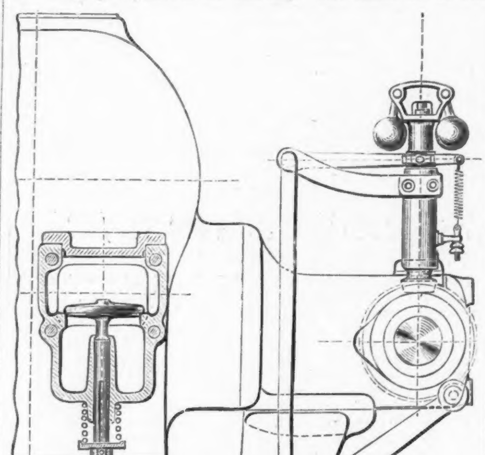


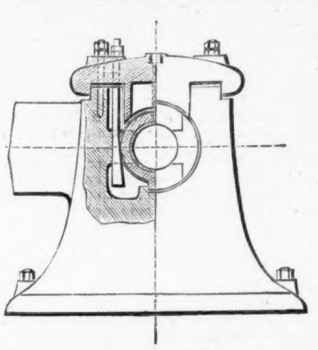


FAC-SIMILE OF ACTUAL ORDINARY WORKING DIAGRAM



FAC-SIMILE OF ACTUAL STARTING DIAGRAM



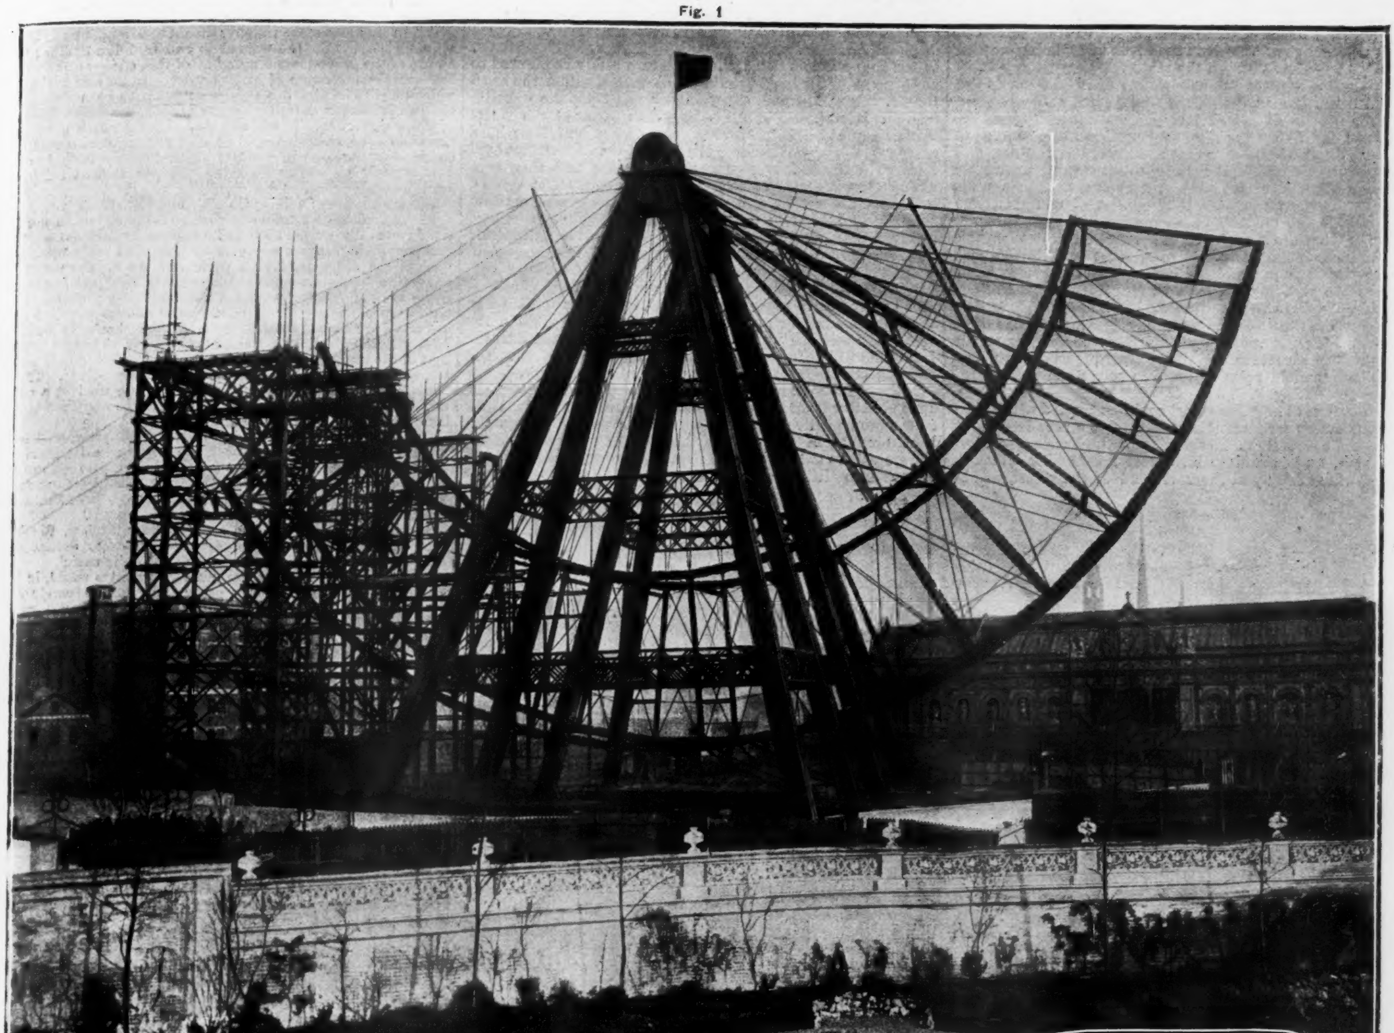


THE gas engine illustrated by the engravings on this page and on this page, show the construction of the improved form of the Robey girder-frame gas engine of 100 effective horse-power. The engine is of the four-cycle single-acting type, the operation of which is now so well known as to need no description. The general design of the engine is well shown by the engravings, and will commend itself to our readers as being well suited to the heavy and impact stresses to which internal combustion engines are exposed. It is another example, in addition to the several we have recently and at different times given, of the growing size and rapid extension of the use of large gas engines. The engine illustrated is started by means of a Clark-Lanchester pressure starter, a diagram from which—or rather from the engine when the starter is used—is shown above. The maximum pressure given by this starter is, it will be seen, about 50 lb. per square inch, and it is an important point that this pressure generated outside the combustion chamber in no case exceeds about 50 lb. per square inch. Barring gear is provided, which enables one man to turn the fly-wheel round to the proper position for starting. The crank is cut out from a solid forging of Siemens-Martin steel, the webs and reciprocating parts being balanced by cast iron balance weights, secured to webs by steel hoops; this being undoubtedly the best method of counteracting the weight of moving parts, and thus enabling the engine to run at a high speed, which is so conducive to economy, without excessive vibration and wear and tear. The practice of balancing by fly-wheel weights is not to be commended for such purposes. The main bearings, see engraving below, are in four parts, and adjustable vertically and horizontally, and are of very ample size. All the bearings are arranged for continuous lubrication without stopping the engine. The engine is provided with an outer bearing, the fly-wheel and driving pulley being placed between the engine and this outer bearing. Improvements have been made with a view to the improvement of the governing of such large gas engines. Hitherto this has been somewhat imperfect, necessitating renewal of the working parts. In the governor and gear as used, the centrifugal governor has only to determine the position of the hit-and-miss finger, which is made of tool steel, and having very broad striking edges is practically indestructible. The work of lifting the gas valve is performed by separate lever and cam, as shown by the annexed engraving.

# THE GIGANTIC WHEEL AT EARL'S COURT

MESSRS. BASSETT AND WEBSTER, LONDON, ENGINEERS

Fig. 1



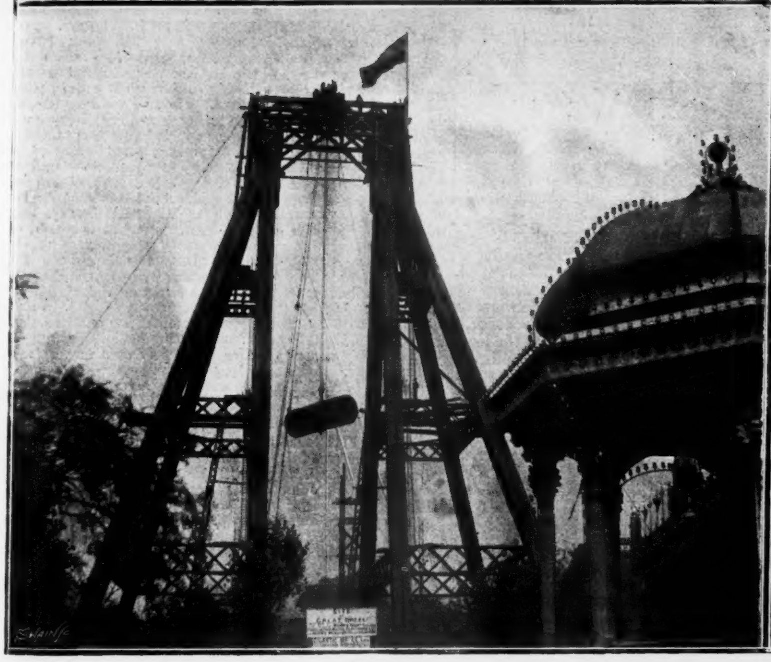


Fig. 2

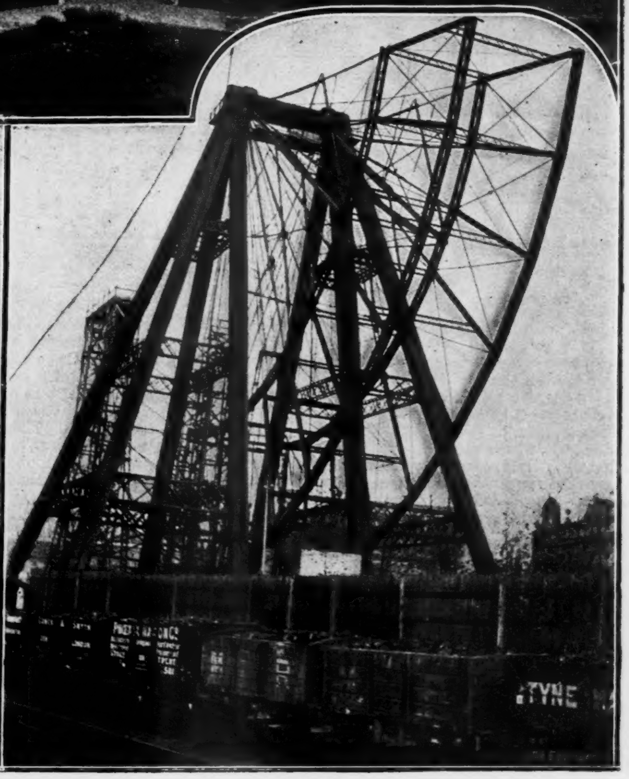

Fig. 3

## THE GIGANTIC WHEEL.

On the 20th of last April, page 324, we described the construction which, under the name of "The Gigantic Wheel," was then being commenced in the grounds which lie between the West Kensington, Earl's Court, and West Brompton railway stations. The progress of this work was considered to be one of the attractions of the Industrial Exhibition, and whilst that was open, the axle was hoisted, and the first few spokes were put in place. Since the closing of the Industrial Exhibition the work has gone steadily on, and is now entering its most interesting phase.

In the illustrations, Fig. 2 shows the framework of the towers completed, and a section of the axle in process of being lifted. In Fig. 3, one quarter of the wheel has been erected. This includes the inner and outer periphery, with spokes, and most of the bracing, but not driving gear or cars. Fig. 1 shows the state of the work on November 30th. Several further sections have been added since that date, and by Christmas, 21 out of the 40 pairs of spokes will be in place. Fig. 4 shows the side and end elevations, longitudinal and cross sections of the great axle. This, instead of being solid, as in the Ferris wheel, is a steel tube, made of plate 1in. thick, and 7ft. internal diameter. The total weight of this axle is 58 tons, and it was hoisted in three pieces. To erect it, a wooden stage was built, forming a bridge from one tower to the other. This gantry carried a line of rails 10ft. 6in. gauge, and the lifting was done by a traveller running on these rails. The plummer blocks were first hoisted, run sideways to their position, and lowered into place. The end lengths of the axle were then lifted and slung, one in its correct position, and the other overhanging for 2ft. Then the middle length was raised, slid into one of the end lengths, and riveted up. Finally, the other side length was drawn over the centre one, riveted up, and the axle completed. They are a fairly tight fit, but were brought together with union screws. As will be seen by the illustration, the two end lengths overlap the middle one for 11in. on each side, and the joint is stiffened by an internal ring of 6in. by 3in. by ½in. T steel. The rings stiffening the ends of the axle are much heavier. Besides an external plate 1¼in. thick, there are, on the inside at each end, six rings of 9in.

by 7in. by $\frac{13}{16}$in. steel joist, of which the outer flanges are riveted to the main tube, and the inner are united by another plate of steel 1in. thick, so that the internal diameter at the bearings is reduced to 5ft. 6in. Close to the inner edges of the bearings, are rings to carry the spokes. These rings form circular girders, being built of $1\frac{1}{4}$in. plate, the outer edge of $4\frac{1}{2}$in. by $4\frac{1}{2}$in. by $\frac{3}{4}$in. angles, and the inner of 6in. by 6in. by $\frac{3}{4}$in. angles. They are in pairs, 3in. apart, so that the heads of the spokes may come between them, the latter being secured by 3in. pins passing through the plates.

The axle was in place and completely finished towards the end of August, and the first spoke was hoisted and connected with it on the 1st of September. By referring either to the drawing of the whole wheel on page 324 of April 20th, or to Figs. 1 and 3, it will be seen that the wheel has an inner and outer periphery; and that the spokes between these two are solidly constructed with plates and angles, whilst from the inner periphery to the axle they consist of comparatively slight rods, being only $2\frac{3}{16}$in. in diameter, though they are 90ft. long. They are brought on to the ground in two lengths, and the ends being screwed with right and left-handed threads, they are joined together by a socket before being lifted. Each rod is suspended in four different places, and hoisted by two tackles simultaneously; but even then they sag very much whilst they are being raised; and until they can act as tension rods, they naturally add nothing to the strength of the structure. On the contrary, it has been necessary to lash scaffold poles to them to keep them straight, as may be seen in Fig. 3.

The question of how the wheel could be erected without an enormous outlay for scaffolding was clearly a very important one for the contractor. The staging of the Ferris wheel was 300ft. high, and is said to have cost £5000. Mr. Basset's staging, which is only at the north end of the wheel, will be 150ft. high when finished, and will not have cost more than £500. It is being built entirely of Devonshire larch, which has been brought to London especially for this work. The first step towards the erection of the spokes and periphery was to put down a very strong anchor in the grounds to the south of the wheel. This is made of two 12in. joists with timber between, entering the ground at about 60 deg., to the depth of 9ft. or 10ft., where they bear against strong cross beams. The first two pairs of spokes were then lifted, and connected with the axle. The segments of the inner and outer periphery which join them were added, including the cross bracing, and the whole was then drawn forward towards the anchor, the axle revolving without any difficulty. A third couple of spokes were added, and then a fourth, till ten pairs, or one quarter of the wheel, had been erected. This stage of the work is shown in Fig. 3. The approximate weight of a quadrant of the wheel is 150 tons, and the strain required to pull it round, when in the most unfavourable position, is 90 tons. For this work two sets of 50-ton blocks are being used, with a Latch and Batchelor's flat-lay corded steel wire rope, $4\frac{1}{2}$in. circumference. Each rope is considered safe for 36 tons, and, as they pass twice through the blocks, the strain on each is only $12\frac{1}{2}$ tons. Mr. Basset has tested each tackle at Messrs. Maudslay's works by lifting 50-ton boilers, filled with water, with them. For making the connection between spokes and axle, a pendulum stage has been hung to the latter, which always remains in a horizontal position however the axle may be turned.

Fig. 4—DETAILS OF AXLE

As soon as the first quadrant of the wheel had been erected by drawing the completed portion forward, spoke by spoke, the second quarter was commenced on the northern side. For this part of the work the axle was not required to revolve. Section after section was built up, the pieces being hoisted from the scaffolding, so that the twenty-first pair of spokes, which are now being put in place, are in a horizontal position, exactly opposite the first pair.

It is evident that if the building were to be continued without other precautions being taken, the periphery would be subjected to strains for which it is not designed. Whether the erection were continued with the axle in its present position, or whether it were turned, all spokes above the horizontal line would cease to be in tension, and would have a tendency to draw the periphery towards the centre. To counteract this struts are being put up in the first quadrant, from the axle to the inner periphery. There are three pairs of struts, placed at distances of one-twentieth of the circumference apart. They are made of squared pitch pine 12in. by 12in., and are 89ft. 6in. long. For a length of 32ft. in the middle, there are scarfs 6in. thick on each side, so that the section is increased to 24in. by 24in. These six strutts are connected in both directions, by five rows of light steel joists, and braced diagonally, also in both directions by $1\frac{3}{8}$in. round steel bars. When they are completed, the wheel may safely be allowed to be turned still further in the same direction, whilst the erection is continued from the top of the staging at the opposite end. It is proposed to put up another quarter of the wheel in this manner, and the first pair of spokes will then have assumed a perpendicular position, and will only be kept straight by the timber struts. Strong chains will then connect the outer ends of the first and the thirty-first spokes, and the wheel will be turned back one-eighth of a revolution. It is not proposed to use timber strutts at the northern end, as Mr. Basset considers that the periphery will be sufficiently rigid to carry itself, whilst the fourth quadrant is being erected. Then the inner ring and inner spokes will be lifted and suspended from the chains. When these are in place the wheel will be once more moved to the position it occupied when the third quadrant was completed, and in that position the rest of the periphery will be finished. It is expected that the last spoke will be in its place by the end of February, provided the weather offers no impediment to continuous work.

Although all the material has been finished long ago, the space to stow it on the site is so limited, that there are still 80 tons to be delivered on the ground. As soon as this has been brought in and erected, the lifts and other work at the towers will be able to proceed; and meanwhile the cars will be put into their places and the rest of the accessories completed. The machinery for turning the wheel is also in hand. It will be driven by two semi-portable engines by Messrs. Robey and Co., each of 16 nominal and 50 indicated horse-power. A third engine by the same makers, for driving a dynamo, is also in position. Instead of the wire hawsers, as described in our previous account, it has now been decided to use chains. These chains will go from the engine-house, through a culvert, to pulleys secured to the further or southern legs, and then round the wheel to pulleys secured to the legs at the northern end, and thence return through the culvert to the engine-house. Each of these pulleys will be provided with an arrangement for taking up the slack, so as to keep the tension equal. The driving motion will be communicated to the intermediate shaft by means of a forged steel pinion, gearing into a wheel with shrouded teeth.

The design and details of this structure are the joint work of Mr. Walter B. Basset, of the firm of Messrs. Maudslay, Sons, and Field; and of Mr. J. J. Webster, who designed the full-sized model of the Eddystone Lighthouse, which was shown at the Naval Exhibition a few years ago.

## THE INSTITUTION OF CIVIL ENGINEERS.

### COLLIERY SURFACE WORKS.

At the ordinary meeting on Tuesday, December 11th, Sir Robert Rawlinson, K.C.B., President, in the chair, the paper read was on "Colliery Surface Works," by Mr. Edw. B. Wain, Assoc. M. Inst. C.E.

As an instance of the development of mining operations during the past twelve years, the North Staffordshire coalfield was cited, where the output had been increased 40 per cent., and this was due to the fact that there was hardly a colliery in the district the plant of which had not been considerably improved during the period referred to. Under the varying conditions consequent upon the increasing depth at which it was necessary to work the coal the work of laying out the surface works was said to have been one of evolution, and comparisons between such works and those laid out recently on modern principles for a definite output would probably indicate much waste and inconvenience resulting from spasmodic and desultory extensions.

It was of the highest importance that the works should be concentrated as far as possible, so as to permit efficient supervision and to reduce the staff of mechanics and general labourers. An example case was mentioned of a colliery, where in 1876 six small and scattered plants were at work on the property, and were raising less than one-half of the material now being obtained from two shafts. As the plant at each shaft required its staff of enginemen, stokers, pit-banksmen and foremen, it was evident that great economy was effected by reducing the number of such establishments. In the instance mentioned, the reduction in surface-charges effected by concentration was 4·67d. per ton.

Where practicable, the railways should be arranged so as to allow a gentle descent for the wagons to and from the screens; if the nature of the ground would not admit of this, endless ropes working between the rails were of great service. In no case ought dead-end sidings to be used if a regular output is to be maintained, as the loss of time in shunting wagons would cause serious hindrance to the coal-winding. It was also desirable that each quality and size of coal should be delivered on a separate road, so as to allow of continuous loading. In a set of colliery sidings so laid out the cost of shunting was only 0·09d. per ton, or about 0·5d. per ton per mile.

The author was of opinion that it was not advisable to undertake new work of importance in colliery workshops, but to use them simply for the purpose of making such repairs as might be necessary. In districts where there were good engineering works near to the collieries, even a portion of the repairs might with advantage be sent out; but where there were not facilities for doing it near at hand, it was of the highest importance that all tools and machinery for maintenance should be provided at the colliery. Where practicable, the workshops should be built on a level with the pit-bank, and light tramways of the same gauge as that of the underground roads should be provided to facilitate the transport of material from the shops to the pit-shaft. The particulars were given of a range of workshops used at a colliery raising 2000 tons per day, with details of the construction of safety lamp room and cost of cleaning, &c., lamps.

Creeper-chains, gravity-roads, and balance-cages worked in connection with double-deck pit-bank platforms were described; also Fowler's hydraulic arrangement for use where more than two decks had to be changed. The most convenient size of pit-wagons was discussed, a gross weight of 18 cwt. to 20 cwt. being mentioned as the maximum which might be conveniently handled.

Four types of tipplers—the ordinary back tipplers, Rigg's and mechanically worked end-and-side tipplers—were described, the side tipplers being considered the most generally useful.

The subject of screening and picking-apparatus would, in itself, afford material for a lengthy paper. The author therefore only briefly noticed some of the types of screen in general use. In laying out the heapstead, it was important that there should be sufficient height between the pit-banks and screen-siding levels. The height would vary considerably according to the type of screen and the number of sizes desired. In general practice it was found that fixed bar screens with not less than 20ft. was required, if the coal was to be separated into three sizes, whilst with jigging screens it was possible to do the same work with 16ft. where no picking-belts were wanted. Fixed bar-screens were said to be objectionable on account of the steep gradient and consequent breakage of the coal in screening. Mechanical screens might be classed under three heads: First, revolving barrel screens; secondly, endless belt screens, such as the Lührig belt and the Greenwell screen; and thirdly, jigging screens. For dealing with a large output from a tender seam, containing a high proportion of small, the author advocated end-driven jiggers with a flat gradient and driven by cranks or cams with a throw of 4in. or 5in., working at about 100 revolutions per minute. The Greenwell screen, suitable as serving both as picking belt and screen, was noted as being specially advantageous where little elevation was available.

The particulars were given in a tabular form of several modern winding plants, with the speed of winding, the average load, and the maximum possible quantity which could be raised per shift of eight hours. An example, a net load of 52 cwt. of coal was raised 550 yards in 44 seconds, with an average speed of $37\frac{1}{2}$ft. per second, and a maximum speed of 60ft. per second. Under such circumstances all complications in the winding engines must be avoided. With the higher steam pressures now used, there should be, however, no difficulty in taking advantage of compound working, provided the high and low-pressure cylinders were both duplicated.

Owing to the variable load due to the decreasing weight of the rope in ascending, and the increasing weight in descending, winding engines were generally wasteful in working. There were various contrivances to balance the load, but the best and simplest was a plain balance-rope worked with a parallel drum.

The economy of fuel in colliery work had received too little attention in the past, the boilers being often supplied with inferior coal or slack which had been considered unsaleable. The amount of coal consumed in colliery work was probably not less than 5 per cent. of the total output of the kingdom, and as slack had now become more valuable, colliery engineers were beginning to give greater attention to the questions of compound working, expansion gear, condensation, and balanced loads. The engines had been as a rule, designed to admit steam into the cylinder for almost the whole length of the stroke. Although such an arrangement enabled the inertia of the load to be more easily overcome in starting, the back-pressure was considerable in the cases of engines running at high speeds, and it was by no means uncommon to obtain from engines working at 80 lb. per square inch diagrams giving a back-pressure of 10 lb. per square inch. The general practice was now, however, to cut off steam at about 20 per cent. before the end of the stroke. Condensation, as applied to modern winding engines, could only be said to have reached the experimental stage, but it was probable that independent surface-condensing apparatus, to maintain a steady vacuum, would be largely used in the future in colliery works.

H.M.S. Magnificent.—The first-class battleship Magnificent was floated out of dock on Wednesday last. Her stokeholds, which will contain eight boilers of the ordinary marine type, will be arranged on Martin's system of induced draught. The propelling machinery is by John Penn and Sons, estimated to give 12,000 indicated horse-power with induced draught. The length of the Magnificent is 390ft. between perpendiculars, breadth 75ft., mean draught 27ft. 6in., the displacement at load draught being estimated at 14,900 tons. The armour-plating is "Harveyised" throughout.

Society of Engineers.—The forty-first annual general meeting of the Society of Engineers was held on December 10th, at the rooms of the Society, 17, Victoria-street, Westminster, S.W. The chair was occupied by Mr. George A. Goodwin, president. The following gentlemen were duly elected by ballot, as the council and officers for 1895, viz.: as president, Mr. Wm. George Peirce; as vice-presidents, Mr. Charles Claude Carpenter, Mr. Samuel Herbert Cox, and Mr. George Maxwell Lawford; as ordinary members of council. Messrs. W. Worby Beaumont, Joseph Bernays, R. W. Peregrine Birch, William Bradford, John Corry Fell, Charles Gandon, Henry O'Connor, and Stephen Sellon; as hon. sec. and treasurer. Mr. Perry, Fairfax Nursey; as hon. auditors, Messrs. Alfred Lass, F.C.A., and Samuel Wood, F.C.A. The proceedings were terminated by a vote of thanks to the president, council, and officers for 1894, which was duly acknowledged by the president. The annual dinner of the society took place on the 12th inst. at the Holborn Restaurant. This was the 41st annual dinner, and a large number of members and visitors were present, including Mr. A. Goodwin, president; Sir Robert Rawlinson, Mr. Alexander Siemens, Professor Henry Robinson, Mr. Arthur T. Walmisley, Mr. A. J. Durston, Colonel Davis, Mr. W. G. Peirce, Mr. G. M. Lawford, and others.

## RAILWAY MATTERS.

It is stated that a French engineer has designed and perfected a compressed air locomotive buffer, which will shortly be put to practical test on an English line.

The North British and Caledonian Railways are engaged in testing rival systems of carriage heating with the view of ascertaining the most convenient and efficient substitute for the foot-pan.

The first sod of the new Snowdon Railway was cut on Saturday last. This new mountain line starts from Llanberis Station on the North-Western Railway, giving direct access to the Snowdon Railway.

The London and North-Western Railway Company have, it is understood, obtained powers to promote a line from Leeds *vid* Gomersall to Mirfield, from which place they will run direct to Liverpool.

Recent heavy rains have done great damage to the permanent way of the East Coast Railway of India. Three small bridges have suffered most. The central piers have been clean washed away, not by a regular stream of river, but by an unusual flow of water.

It is stated that the Manchester, Sheffield, and Lincolnshire Railway Company have a very important Bill to come before Parliament with reference to diverting their railway line between Grimsby and Cleethorpes in order to enable them to construct larger and more convenient docks.

The Brooks Locomotive Works, of Pennsylvania, has for some time been engaged upon an order of sixty locomotives for the "Estrada de Ferro Central do Brazil." The engines are of three types, the Mastodon type, for a track of 3ft. 3⅜in.—1 metre—gauge, the same type for a 5ft. 3in. gauge, and a suburban engine of the same gauge.

A deputation of Liverpool and Glasgow shipowners recently waited on the directors of the London and North-Western Railway, asking for a reduction of railway rates between Liverpool and Manchester, in view of the competition of the Manchester Ship Canal. The directors, however, did not see their way to make any concession.

A Reuter's cablegram from Calcutta says that it is understood that the India-office has now practically agreed in full to the proposals of the Government of India in the matter of further railway construction. The programme arranged a month or two ago will therefore, with only a few reservations, be carried out in due course.

The contract for the construction of the Jamaica Railway has been let to an American contractor, Mr. James P. McDonald, of Knoxville, Tenn. In addition to the ordinary construction work, Mr. McDonald has the following extras, viz., 29 tunnels, 193 girder bridges, 9 truss bridges, and 11 viaducts, some of great size, all of steel, and on piers of masonry.

Excellent results have been given by Holden's system of oil-burning on the Austrian State Lines. The action of the oil is so energetic that the steam pressure of a locomotive heated in this way can be raised in three minutes from three to ten atmospheres, while with coal alone six and a-half minutes are required. On long runs the steam pressure can be kept at maximum pressure, while the engineer has absolute control of the fire, which he can check or increase in intensity as production of steam may require. This method is to be also used on the Metropolitan Railway of Vienna.

Serious inconvenience has this week been caused to those South Staffordshire towns joining up to Birmingham which are served by the South Staffordshire Tramways Company, by a sudden cessation of the service owing to a dispute with the Electric Construction Company as to payment for the working of the trams. The district affected extends fourteen miles in length, eight of which are worked by electricity, and the other six by steam. Complaint has been made by the local authorities of the present state of things, and it is understood that negotiations are being conducted which, it is hoped, may result in an early resumption. The existing difficulty is likely to bring to a head the objections of the West Bromwich, Handsworth, and Wednesbury authorities to the continued use of steam on their portion of the line, and to issue either in the extension of the electric systems throughout the entire length, or the adoption of the cable method through the towns mentioned. The local authorities would prefer the cable system, but the tramway company contend that electricity works much better and is cheaper than any other method.

A circular letter has been issued by the Secretary of the Royal Agricultural Society of England to the members of that society referring to the fact that a conference on light railways has lately been held under the auspices of the Board of Trade, and a committee, on which the society is represented, appointed to report upon the subject. It being desirable that the agricultural aspects of the question should be fully considered, the council desire to receive any suggestions which the members may have to offer on the agricultural light railway requirements of any particular district in which they are interested, and a schedule of questions is given to which answers are desired. These questions are as follows:—"(1) Please state county or counties to which the subjoined observations apply; (2) district to be agriculturally developed, naming terminal towns, places, or stations; (3) description of light railway considered most suitable; (4) the main line of railway, if any, with which a suggested light railway should have connections; (5) how funds for construction and equipment might possibly be provided—by local subscription, by rates, or advances on the security of rates, or by a combination of these sources or otherwise; (6) any other observations likely to prove useful for the purposes of the inquiry."

During the five winter months 25,500 cubic fathoms of earth were added to the embankment on the Western Siberian Railway between the town of Tchelyabinsk and Omsk. According to the *Times* a distance of ten versts of line is ready, and 116 station houses and other buildings are finished. There have been prepared 270,000 sleepers and 4000 transportable "snow-protectors" to prevent the line from being snow-blocked. The manufacturers have supplied over 608,000 puds—nearly 9650 tons—of rails, 37,000 puds—about 587 tons—of fastenings, 12,000 puds—about 190 tons—of water pipes, two water reservoirs, 11 hydraulic cranes, and three turntables of a diameter of 56ft. On the same line from Omsk to the River Obi the survey has been completed for a distance of 142 versts, and the plans have been drawn up. Over 21,000 cubic fathoms of embankment have been made. On the Central Siberian Railway between the Obi and the station of Krasnoyarsk 390 dessiatins—about 426 hectares—of wood have been cut down, and 41 dessiatins—nearly 44 hectares—of stumps have been uprooted. Earthworks to the extent of 25,000 cubic fathoms have been constructed, as well as over 3000 square fathoms of protective escarpment. Five stations and other buildings have been erected. Nineteen versts of the railway and 40 versts of the telegraph wire are ready. The manufacturers have supplied more than 18,000 puds—over 285 tons—of iron for the bridge across the Tom, as well as 140,000 puds—about 2200 tons—of rails, and nearly 44,000 puds—about 700 tons—of fastenings. On this line over 200,000 sleepers have been laid and 6000 telegraph poles erected. Sixty-three versts of the Ussuri line between Vladivostok and the Grafskaya station are complete, and 37,000 cubic fathoms of earthworks have been laid. The second telegraph line is ready for a distance of 45 versts. Thirty-six station houses and other buildings have been erected.

## NOTES AND MEMORANDA.

In a recent number of the *Comptes Rendus* is a paper on the laws of air resistance, by M. E. Vallier. Formulæ are derived which express the specific resistance of a body (*a*) where the velocity is greater than 330 metres, (*b*) where the velocity is between 330 and 100 metres, and (*c*) where the velocity is less than 100 metres per second.

In a report which has just been issued by a Board of United States Engineer Officer on the maximum practicable length of a suspension bridge, they state that using steel wire cables having a tensile strength of 84 tons per square inch, and a factor of safety of 3, the limiting span for a railway bridge to carry heavy traffic is 4335ft. The total suspended dead load in this case works out to about 233,900 tons.

Before the Paris Academy of Sciences a paper was read on the 3rd ult., on the reduction of alumina by carbon, by M. Henri Moissan. The author describes the reduction of pure corundum by means of his now well-known electric furnace. Liquid alumina is not reduced by carbon; the reduction only takes place when the vapours of these substances are carried to a very high temperature, metallic aluminium is then produced and partially combines with carbon.

In a paper on "The Solubility of Ozone," M. l'Abbe Mailfert recently stated that at a pressure of 76 mm. water dissolves two-thirds of its volume of ozone at 0 deg. C., at 12 deg. about one-half. The solubility of ozone in water acidified with sulphuric acid is the same as its solubility in pure water up to about 20 deg. C.; more ozone is dissolved by the acid solution above this temperature. The suggestion is made that oxonised water might be employed as a disinfectant and antiseptic.

In a paper communicated to the *Physical Review*, Mr. S. H. Brackett gives an account of some experiments he has made on the magnetic properties of iridium. The samples used—says *Nature*—contained 98 per cent. iridium, with some platinum, and a trace of phosphorus, but no iron. A bar of the metal 13·3 mm. long, 3·2 mm. wide, and 0·9 mm. thick, when brought into the field of an electro-magnet, set itself at right angles to the lines of force, and became permanently magnetised in a transverse direction, and when suspended, freely set itself E. and W. The permeability of a larger bar was tested, and was found to be unity; and although the specimen was sharply struck while in the magnetising coil, no induced magnetisation was produced.

Mr. Michele's test for Portland cement for 1895 is as follows:—Pats ½in. thick in water, absolutely sound at seven days; tensile strength, 400 lb. per square inch at seven days; fineness, 5 per cent. residue on a 50 sieve. The pats to be gauged on glass, immersed in water immediately, and left there for the whole period. One pat to each three bricks. The test bricks to be gauged by a skilled man, with a minimum quantity of water, and well rammed into moulds. The average of three to be taken, which shall represent about 100 tons or less. The strain to be applied as quickly as possible. The sieve to have 2500 holes per square inch, and to be of wire not less than ·007 of an inch—34 B.W.G.—in diameter. Shaking to be continued for five minutes.

Professor Joly, of the Paris Ecole Normale, who has been making a study of the metal ruthenium, claims it to be, of all known elements, that which presents the most original properties. He recently submitted to the Académie des Sciences several samples of a red colouring matter, resulting from an association not yet definitely determined—oxychloride of ammoniacal ruthenium—giving a tinctorial power equivalent to that of the richest dye materials obtained from coal tar, to that of fuchsine, for instance. A five-millionth part of the substance suffices to colour water. It dyes silk directly, and the colour thus procured is stable. The chemical reactions of this new colouring matter are equally interesting. Acids transform it into yellow, and alkalines bring it back to red.

In their report on the water supplied to London for the month ending November 30th, Professor W. Crookes, F.R.S., and Professor Dewar, F.R.S., say:—"The floods in the Thames Valley during the month of November have been the severest since the year 1821, and it was not to be expected that the water supplied from the river would not show some signs of the flood. The average rainfall at Oxford during November is 2·31in., while the actual rain has amounted to no less than 4·8in., showing an excess of 2·49in. There is one striking peculiarity connected with the rainfall during November. In most exceptionally wet seasons the fall of rain is more or less evenly distributed over the month. The month which has just closed had, however, seventeen days on which no rain fell, and eight other days on each of which less than 2-10ths fell. On the remaining five days—the 7th, 11th, 12th, 13th, and 14th—no less than 4·02in. fell, while the rest of the month must be called very dry, only 0 17in. of rain having fallen since the 14th. The sudden downpour of four inches of rain in five days—amounting to 69½ million gallons per square mile—largely overtaxed the capacity of the river to carry it off, whereas had this amount been more evenly distributed over two or three weeks no harm would have been done."

At the Society of Arts meeting on Monday last, Professor Vivian B. Lewes gave a lecture on blasting explosives. Remarking upon the cause of explosions in dusty mines free from firedamp, he pointed that until quite recently explosions in mines were always attributed to the accidental ignition of mixtures of air and methane, to which the name of firedamp was given, but it was now recognised that explosions in mines might be brought about—first, by the ignition of a mixture of methane and air, in which the former rose above a certain percentage; secondly, by mixtures of air, coal dust, and methane, in which the amount of the last mentioned may be excessively small; lastly, by mixtures of coal dust and air. In cases recently investigated powder was the blasting agent used, and such powder as was employed for this purpose gave, amongst the products of combustion, nearly half the volume of permanent gases in the condition of carbon monoxide, methane, and hydrogen. The experiments and investigations in various colliery explosions made it abundantly manifest that no explosive should be licensed for use in mines unless it could be absolutely proved that it gave off no inflammable products of combustion. He urged the absolute necessity of legislative enactments at once forbidding the use of blasting powder in any coal mines, no matter how free they might appear to be from firedamp or from dust.

Observations on the variations in level of well-water have been made for the last three years at the Observatory of Catania in Sicily, and the first results are described in a paper by A. Riccò and S. Arcidiacono—*Boll. mens. dell' Acc. Cioenia di Sci. Nat. in Catania*, fasc. 37, June 10th, 1894. They classify the movements into progressive, annual and accidental, subdividing the latter into meteoric and geodynamic. The accidental variations of geodynamic origin consist of small abrupt changes of level, generally downwards, which frequently correspond to movements of the ground. Shortly before the eruption of Etna in 1892, and for several months after, the changes in level of the water-surface were extremely irregular. From June 1st to December 31st, 1892, corresponding to thirty-nine groups of earthquakes, there were abrupt changes of level within twenty-four hours in twenty-one cases; there were, *Nature* says, also fifty small but marked changes coinciding with strong oscillations of the tromometer. Somewhat similar observations have been made in Wisconsin, by Professor F. H. King, United States Department of Agriculture Weather Bureau, *Bull*, No. 5. Here the shock was imparted by heavily-laden trains passing less than fifty yards from the well; but the surface of the water invariably rose, sometimes as much as one-tenth of an inch, returning to its former level after a few seconds.

## MISCELLANEA.

The Corinth Canal is once more reported free for navigation.

In connection with the Dortmund-Ems Canal, the river Ems will undergo a thorough "correction" in the Rhede-Papenberg section.

The Brazilian Government has ordered the waterway leading into Santos Harbour, as well as the anchorage ground, to be deepened, and the sandbanks removed.

It is stated that the construction of the Niagara Falls Utilisation having been completed, Professor George Forbes, F.R.S., who has been engaged for the last three years on the work, is expected to return to this country almost immediately.

Messrs. Laird Bros., Birkenhead, launched, on Saturday last, the new torpedo-boat destroyer Dragon. The Dragon is a sister ship to the Contest, launched a fortnight since; she is 208ft. long and 19ft. beam, and her machinery will be similar to that of the Ferret, now ready.

It is stated that a number of inspectors and assistant-inspectors of mines have been appointed inspectors of factories and workshops to enable them to enforce in the pit banks of metalliferous mines, and in quarries, certain provisions of the Factory and Workshops Acts that are applicable thereto.

The optical department of Dr. Schott's works at Jena, Germany, is at present occupied with the casting of an objective for an astronomical telescope, which is to be, when finished, the largest lens in the world. According to the *American Manufacturer*, its diameter will be 110 cm., or about 43¼in.—or 5in. more than the one at the Lick Observatory. The lens weighs about 2000 lb., rough cast, and will cost, when finished, 300,000 marks, or about £15,000.

There are now fifty-three merchant steamships which the Admiralty have the option of equipping as armed cruisers in case of emergency. Of this number eleven only, according to the *Times*, are in receipt of annual subventions, the remainder being at the disposition of the Admiralty without further subsidy. The Admiralty have just been furnished with a report that of this auxiliary fleet four can maintain an ocean speed of over 19 knots, and five over 17 knots, 37 over 15, and the remainder nearly 15 knots.

A plan recently suggested by Mr. Geo. F. Cole, Chicago, to obviate the difficulties met with in the construction of the Panama Canal consists, of a tunnel through which ships can pass if their masts are specially constructed to collapse either telescopically or by being hinged. A ship entering would pass between a pair of cranes, the yards having been first placed in a vertical position by the crew, and the masts would be lowered to be raised again by a similar pair of mast cranes on emerging. We fear that shipowners might consider this more pretty than practicable.

Messrs. William Wilkinson and Co., Holme House Foundry, Wigan, have completed and set to work a large pair of horizontal underground pumping engines, to deliver 60,000 gallons an hour to a vertical height of 600ft. The engines are compound, working at 100 lb. boiler pressure, cylinders 32in. and 60in. diameter by 36in. piston stroke. Quadruple pumps, 10½in. diameter by 36in. stroke; steam carried down pit shaft from surface, and exhaust brought up to the surface and condensed there by separate condensers and air pump. The total weight of the engines complete is 110 tons, including 16 tons of forgings and wrought iron work, and 5575 lb. of brass work.

The official trial of her Majesty's torpedo-boat destroyer Ardent took place on Saturday last. The Ardent is 200ft. long, 19ft. wide, and 14ft. deep. The first run was made against tide, the time occupied being 2 min. 22 sec. The revolutions were 393 per minute for the starboard engines and 397 for the port. The next run, with tide, was made in 1 min. 59 sec., the revolutions being 390 and 400 for the starboard and port engines respectively. The next two runs against tide were rather better than the first, the time for each being 2 min. 19·4 sec., but the corresponding runs with tide were not quite so good as the first. The maximum revolutions during the trial for both sets of engines were made on the third run, the rate being 404 6 per minute for the starboard and 406·7 for the port engines. The mean speed for the six runs was 27·843 knots. The mean speed on the whole run was just on 28 knots, actually 27·971 knots.

A lock with a total lift of 140ft. is proposed as a substitute for the flight of sixteen locks on the Erie Canal between West Troy and Cohoes. At present two to three hours are required for the passage of those locks, the delay being especially great because the locks are all single length. Thus far, says the *Engineering News*, forty out of the remaining seventy-two locks on the Erie Canal have been enlarged to double length; but to carry out this improvement on the flight of sixteen would be very difficult on account of lack of space, increased demand for water, and the great expense involved. The proposed high-lift lock would consist of two steel tanks, each large enough to contain a boat and its consort, or equal in capacity to the largest locks now in use on the canal. The two would balance each other, one ascending as the other descends, so that the only power required would be that necessary to overcome the friction of the machinery. The scheme is being investigated by the State Engineer, Mr. Campbell W. Adams.

The following specimen of Admiralty cheeseparing we abstract from the *Naval and Military Record*:—"As far back as April last the gunboat Sharpshooter, when returning from a steam trial, was compelled, on account of serious defects to her steering gear, to have towing assistance. The service was rendered by the Government tug Trusty, the master of which piloted the Sharpshooter into the Hamoaze. A report of this special duty was sent to headquarters, and the officer received, as pilotage fee, the sum of £10 4s. Since then the case has been reviewed, and the Admiralty point out that the service regulations state that the master of a tug, when employed in towing and piloting a ship into or out of his own port, is not entitled to any allowance for pilotage, unless the draught of the ship towed exceeds the maximum draught of his own vessel. At the time the service in question was rendered, the Trusty's maximum draught was 12ft., whilst that of the Sharpshooter was a foot less. Under these circumstances their lordships have ordered that the amount paid to the master of the tug is to be deducted from the salary due to him at the end of the year."

A conference has been recently held at the Board of Trade between the electric lighting companies and various local authorities with reference to the proposals of the electric lighting companies to place beneath the public streets and footways electric transforming chambers, and as to the conditions under which such chambers should be allowed to be made. Representatives of various vestries and electric lighting companies attended. In the course of the proceedings it was suggested that the Legislature never contemplated in authorising junction boxes to be placed beneath the streets, that the much larger space involved in the formation of transforming chambers should be permitted. It was urged on behalf of these authorities that the existence of the transforming chambers would be a source of great public danger, inasmuch as it would be impossible to construct them of a water-tight character, that there would be a risk of gas and water leakage and consequent explosions and electrolysis. It was therefore contended that the chambers should not be allowed to be placed under the public streets, and that the companies should, if necessary, obtain private property in which to construct them, and pay rent for such property.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

E. B. D.—*The figures should read 1050ft.*

N. D. P. (Swan)—*Try wrought iron welded tubing, which can easily be obtained from several firms. It will probably last a considerable time, certainly much longer than cast iron.*

J. S. (Chester)—*The methods of moulding and the mixtures used you will find in "The Ironfounder," by S. Bolland, published by John Wiley and Sons, New York, and in England by Gay and Bird, London.*

W. O. G.—*You can calculate the stresses for yourself. Multiply the weight by the square of the speed, and divide by thirty-two times the radius of gyration. In your case the distance from the centre of rotation to the centre of the thickness of the piston may be taken for the radius with sufficient accuracy. By setting out on a drawing board the piston in various positions you can easily obtain the stresses.*

J. B. J. (Manchester).—*We fear you have read books on the steam engine to small purpose. You have evidently not mastered the principle of expansive working. None of the forms of steam engine which you have sketched is necessarily more economical than the others. You should consult such a book as "Bourne on the Steam Engine," which you can see in your Free Library. A very good elementary explanation of the principle will be found in Lardner's treatise on the steam engine, in Weales' series. You can see in the Patent Museum, South Kensington, a sectional model of such an engine as that shown in your sketches No. 2 and No. 3. It was patented more than forty years ago.*

### TENDERS AND ADVERTISERS.

(*To the Editor of The Engineer.*)

Sir,—We shall be glad to know whether any of your correspondents have had any experience similar to the following:—(1) An advertisement appears in The Engineer, inviting tenders for certain work; specification and tracings on receipt of a deposit of so many guineas, applications to be addressed to an engineer, a M. Inst. C.E., in a certain part of England. (2) Cheque duly received and cashed, but no specifications or drawings sent. (3) Delays and all kinds of excuses, extending over several months; but still no specifications or tracings sent, and no return of the deposit. If any of your readers have had similar experience, we shall be glad to get into communication with them through you, in order that we may take concerted steps to insure the return of our money, and to expose this method of doing business. Manufacturer.

London, December 19th.

### DRYING FUEL.

(*To the Editor of The Engineer.*)

Sir,—We are desirous of ascertaining the best known system of drying cylindrical blocks of fuel about 2½in. by 2½in. which contain, say, 25 per cent. moisture. There would be no objection to the flue gases passing over the blocks. Any information which your readers could give us as to the quickest and most economical process would be much esteemed.

London, December 13th. T. A. M.

### SUBSCRIPTIONS.

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*

*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers)*.. .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

### ADVERTISEMENTS.

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

### DEATH.

On December 14th, at 29, Lightfoot-road, Hornsey, London, Benjamin Williams, mining engineer, formerly of Goldsithney, Cornwall, aged 65 years.

### MEETINGS NEXT WEEK.

Royal Institution of Great Britain.—Thursday and Saturday, December 27th and 29th. Paper: "The Working of an Electric Current," by Professor J. A. Fleming, F.R.S., M.R.I.

# THE ENGINEER.

*DECEMBER* 21, 1894.

## HIGH-PRESSURE COMPOUND ENGINES.

By a fortunate coincidence, very shortly after the publication in our issue of the Nov. 23rd, containing an article on "Practical Steam Engineering," we received an advance copy of a paper to be read at the December meeting of the American Society of Engineers, by Mr. F. W. Dean, of Boston, giving particulars of "Trials of a Recent Compound Engine with a Cylinder Ratio of 7 to 1." It will be remembered that we pointed out that high pressure and long range of expansion represented the never-failing combination which in practice secured economy. Mr. Dean's paper amply verifies the accuracy of our statements and the soundness of the opinions we have expressed. It can scarcely have escaped our more observant readers that of late little or nothing has been heard about the influence of range of temperature and its effects on economy. This is natural enough. That reduction of range should diminish cylinder condensation appeared to be obvious, and it was argued that in the triple-expansion engine, cylinder condensation must be much smaller in amount than it would be in a compound engine. But the experiments since carried out by many persons, Professor Kennedy in particular, proved that in this case at all events, theory and practice do not coincide, the cylinder condensation in triple-expansion engines being quite as heavy as in any other reasonable type of engine. When, indeed, we come to consider that the reduction in range can only be obtained by largely increasing the amount of metallic condensing and re-evaporating surface, it is difficult to imagine how it has been possible that the extravagant notions formed by some persons concerning the triple-expansion engine could have been conceived. The truth is that the triple-expansion type has been more economical than the compound simply because the former works at higher pressure and greater range of expansion than does the latter, and, as we have said, this condition is sufficient to secure economy. In the same way the quadruple-expansion engine will, no doubt, prove better than the triple-expansion engine, not because it has four cylinders, but in spite of that fact, solely because a higher pressure of steam will be used and a much greater range of expansion.

If, now, the views we have thus expressed are really sound, then we should expect to find a compound engine working with high-pressure steam just as economical as any other type of engine working within the same limits of pressure and back pressure. Unfortunately, there is not as yet much evidence in this direction available. We may cite Mr. Asplin's experience with the steamers of Messrs. Leyland's line; but that is limited to a general practical result, which is that the compound engines of such boats as the Minho are, on the whole, as good as triple-expansion engines. It is worth notice that some eminent makers of engines in the North have recently tendered for large electric light compound engines with a cylinder ratio of 1 to 6, and 180 lb. boiler pressure. But these engines have yet to be built. Mr. Dean has, however, supplied us with evidence which, so far as it goes, is conclusive, a cross compound engine indicating nearly 600-horse power using but 12·84 lb. of dry saturated steam per horse per hour. This is a result which has hardly ever been beaten save by a few triple expansion engines working under very special conditions. The engine tested by Mr. Dean has cylinders 18·44in. and 48·5in. in diameter. The stroke is 4ft. The piston speed was 612ft. per minute; the average pressure close to the engine 159 lb. above the atmosphere. The engine was specially built by the Wheelock Engine Company, of Worcester, Mass., for Messrs. Knight, of Providence, to drive a mill in Natick. The cylinders have a volume ratio of 7 to 1, which, Mr. Dean tells us, is held to possess a special virtue. The trials appear to have been carried out with the greatest possible care on January 26th and 27th. The first trial lasted four and a-half hours, the second five hours. More time was not available, because the engine was doing its regular work in driving the mill. No attempt was made to weigh coal. All the feed-water was weighed, not measured. During the first trial, 34,089 lb. were used; during the second, 37,677 lb.—quantities so large that even a considerable error would be a small percentage of the whole. The engine was 400ft. away from the Babcock boiler, which was quite distinct from the rest of the boiler plant. There was a steam separator close to the engine, and a calorimeter was placed between it and the valve chests. The percentage of moisture was under 2. The high-pressure cylinder is jacketed all over; the low-pressure covers only. Between the cylinders is a re-heater—which, however, seems to have been comparatively inoperative, the surface being inadequate. The vacuum was only 25·4in. and 25·2in., although the condensing water was very cold. The condenser was of the injection type, but did not perform very well. The jackets seem to have been badly piped, and Mr. Dean states that the circulation in them was probably not good. Thus it will be seen that in certain small matters the engine was deficient in those particulars which secure the highest results. Nevertheless, the engine gave results altogether excellent. The diagrams are very good, as was to be expected from valves working with Wheelock gear and a clearance of only 2·75 per cent. in the high-pressure and 2·5 per cent. in the low-pressure cylinder.

In considering the causes which conduced to these results, we find that in the first place the pressure was very high, and in the second the range of expansion was unusually large, amounting by volume to not less than 33 to 1 on the 26th January, and 33·4 on the 27th January. The initial cylinder pressure as given by the indicator was 168 lb.; the terminal in the low-pressure 5·4 lb. absolute in one set of diagrams, this is a ratio of 1 to 31. In other diagrams no doubt the pressures gave the result stated by Mr. Dean as the average. So far as we can learn, the working of the engine was in all respects quite satisfactory. Mr. Dean holds that the large intermediate receiver augmented drop and caused loss, but on this point we do not agree with him. It would certainly have been impossible without such a receiver to have maintained the back pressure in the high-pressure cylinder so uniform as the diagrams show it to have been. Mr. Dean holds that better results might have been got had the vacuum been better. "Although," he writes, "the performance of the engine is remarkably good, I believe that it was realised in spite of great defects, and that it would have been much better if these defects had not existed. The economy, in my judgment, is due to high steam pressure, with the resultant high degree of expansion, small clearances, and tight pistons and valves." This is to all intents and purposes our own opinion.

It will be seen that such results open up an encouraging prospect for many mill owners. Triple-expansion engines are not very convenient for mill work. The cotton mill engine always has either one or two cranks. The favourite type is the horizontal cross compound. To secure a considerable saving in steam, it would seem to be sufficient to line up the existing high-pressure cylinder, or to substitute a new one, and to put down new boilers carrying 150 lb. or 160 lb. instead of the present boiler carrying 90 lb. or 100 lb. With good coal and economisers, there ought to be no difficulty in evaporating 9 lb. of water per pound of coal. This, with 13 lb. of feed-water per horse per hour, would give a coal consumption of less than 1½ lb. per horse per hour. At this rate the cost of the alteration would soon be repaid. It seems to us that it would be worth while to push the experiment begun in Liverpool and continued in the United States further here. The advantages of the compound engine as a machine over the triple-expansion engine are sufficiently obvious not to need explanation.

In marine work, while for small power the compound two-cylinder type would answer very well, for large power it would be no doubt necessary to resort to three cylinders, otherwise the diameter of the low-pressure cylinder would be too great. We should thus revert to engines of the Etruria type, with one high-pressure cylinder and two low. It is worth notice that the Etruria's boilers carried 120 lb. pressure, which is very high for a large compound job, and yet the performance of her machinery has been altogether satisfactory. If the pressure had been 160 lb.—the high-pressure cylinder being in proportion smaller in diameter—it is probable that no one would have thought of substituting triple expansion engines for the compounds. The objection which has been raised to admitting steam of a very high pressure on to a large piston has no force in such a case, because the high-pressure piston is reduced in diameter; and for the rest, improved materials and methods of construction, the use of steel for pistons instead of cast iron, and so on, have eliminated all cause for apprehension as regards power to bear stresses. We repeat that, so far as can be seen, the high-pressure compound engine is full of promise of success, and we hope that experiments will be undertaken in this country to settle whether that promise will or will not be fulfilled.

## THE END OF A TRADE UNION.

The National Amalgamated Sailor's and Firemen's Union has ceased to exist. The Union owed, it is said, £3871, and had in hand £210 to meet its liabilities; at least that is the statement made in the balance sheet for the Board of Trade. The Union has had a short, stormy, and mischievous life. Its history is instructive as an example of the lengths to which the tyranny of unionism can be pushed, and an illustration of the power which lies latent in the nation for maintaining freedom. The Union was got up by Mr. Havelock Wilson, who kept a little coffee shop in High-street, Sunderland. The first meeting of the Union was held in August, 1887, and almost from the beginning it assumed tyrannical powers. Mr. Wilson is an energetic man, and he acquired great influence over a class which is certainly not the best educated or the most intelligent in the country. Strikes were ordered and took place. The Union men refused to sail with the non-Unionist. At one time there were more than 60,000 men on the books of the Union. They had power and they exerted it. Mr. Wilson boasted that he was able to make every sailor and fireman pay into the Union whether he belonged to it or not. The condition of the Union funds goes to prove that this was a vain boast. Meanwhile the shipowners took apparently little notice of the Union. Indeed, the policy of Mr. Wilson was, in the first instance, to let the shipowners alone and get as many members as possible. His operations were conducted rather against the men than the masters. His object was to get the whole seafaring population of Great Britain into the hollow of his hand, and then dictate terms to the shipowners. If he had succeeded he would have controlled the seagoing carrying trade, and with it the commerce of the country. In pursuit of this object, and rendered bold by preliminary success, he at length attempted to draw the officers and engineers into his net. He ruled that no crew should sail in a ship the captain, mates, and engineers of which did not hold his "ticket" or licence. Then the shipowners awoke and bestirred themselves. In August, 1890, they formed the Shipping Federation, and they prepared to fight Mr. Wilson on his own ground. They flatly refused to take only men with the Union ticket. They allowed no distinctions. They took Union and non-Union men alike. When the former having signed articles, refused to sail with the non-Unionists, the Shipping Federation prosecuted them to conviction. It was in vain that great strikes were got up in the Bristol Channel ports and elsewhere. It was all to no purpose that Mr. Wilson stormed and raved and denounced the Federation. Thousands of men who had been coerced into joining the Union refused to starve; they deserted Mr. Wilson and signed articles. Disaster followed disaster. The Union has ceased to exist, and Mr. Wilson has only the satisfaction of knowing that he is still a Member of Parliament. A new Union with, appropriately enough, offices in Jeremiah-street, Poplar, has been formed, and such members of the old Union as remain, and its officers, have been enrolled on the lists of the new body. The theory seems to be that in this way the debts will be discharged without giving the creditors anything. It is open to doubt, however, that this theory can be put into practice. Meanwhile certain statements concerning Mr. Wilson are floating about which, for his own sake, he ought to answer.

It would obviously be impossible to carry on the commercial operations of a great country if the control of those operations rested in a single individual. It is not easy, however, to see how such mercantile conditions could fail to come into being if Mr. Wilson had succeeded in leading his army to victory. The modern sailor comes from almost every country on the face of the earth, and so far as Great Britain is concerned, he has no national ties. Norwegians, Danes, Lascars, Russians, and negroes will fight each for his own hand, without the smallest regard for Englishmen or English interests. It is true that there is a large number of English sailors and sailormen who go in steamers; but these are found for the most part in the ships of great mail lines, and in correspondingly superior positions. To find Englishmen afloat we must go to the quarter-deck; they are all too scarce in the forecastle. But no matter what the nationality of the men who handle ships sailing under the British flag, they do their work, and they must be left free to do it. The heterogeneity of the crews with whom he had to do was at once the strong and the weak element in Mr. Wilson's programme. On the one hand, these men are very ignorant and easily led by promises. On the other hand, they have no fellow feeling or bond to hold them to each other. Thus, they could easily be persuaded to unite; but the task of keeping them together subsequently is not easily performed. Sporadic mischief they may easily be persuaded to do; for sustained effort they are not suited. The weakest element, however, in the Union was want of money. It used to be said of naval officers in the early years of the century that they often paid their debts with the fore topsail sheet, which was a polite way of saying that when pressed for money the captain put to sea and went to another port. The difficulty of getting money out of a forecastle hand is proverbial. Mr. Wilson seems to have had little success in the way of getting in subscriptions; and strikes with no strike pay are like "Hamlet" with the Danish Prince left out. No doubt the shipowners argued very much in this way, and attached less importance to the Union than it deserved. They did not take account with the strong individuality of the leader; or the somewhat sheep-like nature of the men, who, receiving abundant promises of good times to come eagerly, followed their leader without asking too many questions. If the Federation had been formed sooner there would have been less mischief done. In the shipping trade above all others it is essential that the principle of free labour should obtain. A ship has been compared to a factory, but this is no real analogy. The movement of the ship from port to port; the varying conditions under which she is employed; the rigid rules laid down by the Board of Trade for, not diet alone, but a hundred and one other things; the protective legislation which surrounds the sailor, all represent conditions which are quite unlike any that can be found in a factory. If there is a strike at one port the ship can go to another. If men strike having signed articles, their punishment comes sharply, promptly, and surely. The importance of seafaring men has been recognised and acted upon by Parliament after Parliament. The sailor is lifted out of the ordinary category of working men, and if he is to be deprived by a Union of the power of signing articles when he thinks fit, and for any pay he pleases, he will practically be deprived of liberty altogether.

The action of the shipowner is very instructive. In this, as in every other country, there is a great body of public opinion which, as a rule, never makes itself heard or felt. It is represented, for instance, by voters who do not go to the poll. These men really hold the Government of the country in their own hands. Now and then they exert themselves. When they do they make themselves felt. In the same way the employers of Great Britain have vast powers which they seldom exert. That this power should be exercised tyrannically is in the present day impossible, whatever Union leaders may say. Public opinion on the one hand, self-interest on the other, to say nothing of meritorious feeling, would step in and prevent injustice. To say the least of the shipowner, he has at all times fostered freedom of contract. He has not refused to employ a man either because he held a Union ticket or did not. It is noteworthy that a great common danger was needed to secure a great combination. Mr. Wilson has succeeded in not only calling the Sailors' and Firemen's Union into existence, but the Shipping Federation as well. Henceforth the relations of the sailor and the shipowner are placed on a new footing—it remains to be seen whether for good or evil. We believe that the formation of the Federation will do good by steadying trade. Strikes among dock labourers, sailors, and firemen have always been peculiarly disastrous. In their nature they must be local, and the harried shipowner or merchant simply leaves one port for another, and so trade is lost to a port. The very men who strike at Hull will go to Sunderland and work for the wages which they will not accept at the first-named town. When Southampton was the scene of a strike, the dock labourer sought work elsewhere. But none the less the port suffers. London has not yet recovered from the disastrous trade warfare carried on a few years ago. When it is known that the shipowners are powerful, it is less likely that wanton strikes will be undertaken lightly at the beck and call of ambitious men of the Wilson type. But the better trade is, the better will life be for the sailors and the firemen. Combinations, whether of men or masters, are fraught with risks. They must be regarded as necessary evils. But, after all, public opinion is so powerful now-a-days that the risk is minimised. In any case, great or little, it is worth incurring if by incurring it liberty is secured. Our ocean carrying trade is of too much value to be permitted to fall into the hands of demagogues. A union of shipowners is the best security against the occurrence of such a deplorable event.

### THE PARIS METROPOLITAN RAILWAY.

The antagonism that has long existed between the Municipal Council of Paris and the Government is responsible in some measure for the rejection of the project that was recently presented to the Council by M. Barthou, the Minister of Public Works, for the construction of two transverse lines across the city in connection with the Ceinture and all the main lines having their termini in Paris. The scheme had been so carefully prepared, and seemed to fulfil all the conditions of a Metropolitan in such a satisfactory manner, that its rejection has come as a surprise to everyone. The Council states that it will have nothing to do with the scheme on the following grounds. It places too much power in the hands of the railway companies, who would have authority to construct that part of the system in which they would be immediately interested, and the Council contends that the whole of the Metropolitan, being an essentially local work, should be carried out by private enterprise. This is a point upon which the Council and the Government have been in conflict on many previous occasions. It is also asserted that the project does not sufficiently serve the interests of the central quarters of Paris, and notably the Rue Reaumur, upon which the Council has already spent a large sum of money, and it is further urged that the benefits accruing to the Council from the carrying out of the scheme would not compensate it for the loss, amounting, it is estimated, to £1,200,000, that would result from the proposed free admission of the material to be used in the construction of the railway. Some other points of minor importance are also raised against the project, and it has consequently been definitely rejected. It is not now believed possible that the Metropolitan will be completed in time for the Exhibition of 1900, in which event it is difficult to see how the vast amount of traffic that will take place during that period can be dealt with. The only hope of the Metropolitan now lies in the possibility of the Government being able to rapidly draw up and pass another project that will receive the approval of the Municipal Council in time for the work to be put in hand during next year; but it is the general impression that the Council is entirely opposed to a scheme of any sort that will facilitate a displacement of population from the centre of Paris to the suburbs, and that the Government will be too busily occupied next year with the preliminary works in connection with the Exhibition to be able to pay any more attention to the underground railway.

### AMERICAN TIN-PLATE MANUFACTURE.

Whatever the Welsh tin-plate manufacturers may think of the position, and however much they could wish that it was otherwise, there would seem to be no manner of doubt that the making of tin-plates in America is a growing industry. The United States ironmasters having once determined upon taking up tin-plate production, seem resolved to go on with it, whether confronted by tariff reductions or strikes by workpeople. Returns issued by the American Treasury Department for the fiscal year ended June last, and only now available, show that in that period American manufacturers turned out of tin and terne plates from native-made black sheets, 9,000,334 lb. weight in excess of the net imports. The total production was 88,642,000 lb. For the completed year 1893 the total make from imported and American black plate alike was 123,606,000 lb., of which 54,337,000 lb. was from native black plate. In 1892 the aggregate output was 42,119,000 lb., of which more than one-half was from native raw material. In the latter half of 1891, where the industry took its rise, the make was only 2,236,000 lb. weight. It will thus be seen what gigantic strides are being made in the business. Forty firms have now established themselves as tin-plate manufacturers, of which twenty describe themselves as using solely American plates; fifteen as using both American and foreign plates, and five as employing foreign plates entirely. But it is not alone the tin-plate industry which is growing. Production of American black plate is increasing vigorously. The figures for 1893, and for the first six months of 1894, are as follows:—1893, 71,673,000 lb.; first half of 1894, 67,935,000 lb. Thus, the make of black plate in the first portion of this year has almost equalled the whole output of last year; and it is considered certain that the totals of the last half of the year will be even more favourable.

### LOCOMOTIVE COAL.

It is now certain that in the next year there will be a considerable reduction in the cost of the coal for locomotive power for the railway companies in the north-east of England. Where a year ago the scarcity of coal through the strikes caused about 8s. 9d. to 9s. per ton to be paid for coal for locomotive purposes, tenders that are accepted for the coal for next year's supply are from 9d. to 1s. per ton lower, which is a reduction that will have the effect of reducing the total cost in an appreciable manner. When the coal bill for the supply for locomotive power purposes is £26,000 monthly, the largeness of the reduction will be at once evident. Nor is the alteration an unfair one to the coal-owner, for it is certain that the selling price of some kinds of coal has fallen more since the end of autumn lessened the demand for coal for shipment. At present in the North best steam coal is quoted about 9s. 3d. per ton; and if to the 8s. per ton for railway coal, free into wagons at the collieries, there be added the cost of the carriage to the shipping port at which it is sold free on board for 9s. 3d. per ton, it will be seen that the railway price is a good one; whilst the coal-owner has the advantage of having a contract which is not liable to be disarranged by storms such as sometimes affect the ability of buyers of coal for shipment to provide steam tonnage as promptly as is sometimes needed to keep collieries fully employed. Altogether, the prospect of cheaper coal is one that will benefit the railways at a time when demands increase in other directions; and it should lead to an increase of consumption, as cheaper fuel allows a fuller use for purposes of manufacture which have been impeded in districts for want of cheap coal in the last year or two of strikes in the coal trade.

## LITERATURE.

*Charpenterie Métallique Menuisirie en Fer et Serrurerie* Par J. Denfer, Architecte, Professor A. l'Ecole Centrale. Tome premier. Paris: Gauthier-Villars et fils, Imprimeurs-Libraires. Quai des Grands-Augustins. 1894. Tous droits réserves.

The volume before us is one of the most recent additions to the well-known "Encyclopédie des Travaux Publics," which comprises some sixty valuable works relating to nearly every branch of the engineering profession. It might perhaps be considered by some readers that a couple of chapters are devoted to subjects which more strictly pertain to the province of the architect and the builder than to that of the engineer, but the extensive scale upon which steel and iron are employed—the only materials allowed by the author—the numerous forms, simple and compound, into which they are cast and wrought, and the heavy loads to which they are subjected, bring them fairly within our own domain. As an excellent and appropriate example of our meaning, we may mention the new Parcels Office of the Great Eastern Railway at the Liverpool-street terminus, recently illustrated and described in our columns.

In treating in Chapter I. of the general properties of both natural and artificial steel and iron, M. Denfer divides the former metal into seven separate classes, and assigns to each its especial *rôle* in production, manufacture, and construction, from the hardest cutting tool to the mildest drawn wire. While no doubt, so far as the extremes of this division are concerned, there prevails no marked disagreement, yet with respect to some of the intermediate gradations, different nations are not by any means at one. The Germans, for instance, in their bridges and other constructive designs, employ steel of a quality very much milder than that hitherto in use among our engineers, and consequently consider our unit strains too high. They are certainly too high for the German steel, which is obviously inferior to our own, and leads to the conclusion we have expressed on a former occasion, that they do not know in that part of the Continent how to produce steel of a quality that will stand our unit standards. It is possible that while able to actually produce it, the Germans cannot reduce the cost of the manufacture within marketable limits. The remainder of this chapter treats of every form of rolled iron, from rails to sash bars. It is stated that the flanged, or Vignoles rail, is the section most in use. In France, yes; but not in England, where the double-headed rail in heavy sections is preferred. The somewhat peculiar form in the shape of a truncated V inverted—termed "Zorès," from the name of its inventor—though much used in the platforms of bridges, has not yet supplanted the ordinary rolled joist with its simple equal upper and lower flanges. *Fer tubulaire* is a name sometimes given to rolled joists of the Zorès section. Amid the multitude of examples of this description of ironwork, all of which are drawn to a large scale and fully figured with dimensions, we do not find the *fer à coulisse*, which was the section employed for the principal joists in the construction of fireproof floors in France some years ago.

Chapter II. treats of the stresses to which columns, beams, and girders are subjected under different conditions of loading, of which both analytical and graphical demonstrations are given. The formulæ are those usually applicable, but in some instances might be simplified, as at page 68, where, instead of the equation as there represented, the shorter one might be used in which

$$\mu = \frac{p \times a\,(l - x)}{l}$$

At page 70, $\frac{p\,l}{2}$ should obviously read $\frac{p\,l}{4}$, and at page 171 the cube of $d$ is written instead of the square. After determining the moments of inertia for the various sections usually employed, the subject of the practical determination of the dimensions of them is entered into. To facilitate the calculation, a series of careful and laborious tables, occupying some sixty pages, have been made available.

Since the moment of resistance is the maximum bending moment to which a bar may be safely subjected, and the latter is represented by the general equation $\mu = \frac{I}{V}$, then, if $\mu^1$ be the moment of resistance and R the safe maximum working unit stress of the material,

$$\mu^1 = R\,\frac{I}{V}.$$

From this equation the values for $\frac{I}{V}$ are calculated and inserted in their proper column, and the moment of resistance is readily obtained by simply multiplying by R. But in order to render all calculation unnecessary, in the tables are given the safe loads for each bar, or other form of section, for spans varying from 3ft. to 33ft. The bars are supposed to be supported at both ends at the same level, and the load to be uniformly distributed. Should the load be applied at the centre, it is a simple matter to double it, and the conditions of the tables are complied with. The first series of tables relates to round and square bars, and flat thin sections set on edge; c the value for R, for both compression and tension, is made equal to 4·36 tons per square inch. In the other columns the dimensions, the weight per lineal unit, and the gross sectional area are tabulated.

Under the conditions already assumed, if P be the total load and $l$ the span, the greatest bending moment will be at the centre of the bar, and expressed by

$$\mu = \frac{P\,l}{8},$$

which will equal the moment of resistance, and consequently we have $\mu = \mu^1$, or substituting their repective values,

$$\frac{P\,l}{8} = R\,\frac{I}{V}.$$

In the tables R is equal to 7, so that

$$P = 56\,\frac{I}{V} \times \frac{1}{l}.$$

From which formula the safe loads corresponding to different spans can be obtained, or those two data known, the value of $\frac{I}{V}$ can be ascertained by inspection. It is doubtful whether the elaborate set of tables, occupying thirty pages, compiled for the calculation of the moments of resistance of ordinary built-up plate girders, are of much practical use. The author states that in the first place it is necessary to find the maximum bending moment to which the girder will be subjected. Once this calculation is made, the arrangement of the built-up section presents no difficulty, and besides, the general dimensions of girders of this class are frequently determined by other than theoretical considerations, and for which tables are useless.

Chapter III. is of a more practical character than its predecessor, and relates to the building up or putting together of the various component members which constitute in the aggregate a girder, truss, or other description of metallic framework. Semicircular, "drop of tallow," coned and countersunk rivet heads, are described and illustrated, but neither the segmental nor the cheese-headed form is mentioned. The "drop of tallow" shape answers to our ellipsoidal head. Lap and fish plate or butt joints, double and single, are briefly alluded to, but there is no analysis or any attempt made to delineate the best and most economical form. The different methods of joining various sections of iron in one, or in several planes, are well shown in numerous cuts, although some of these combinations convey the idea that they represent, as in Figs. 96 and 103, examples rather of the nature of a *tour de force* than of a real practical joint. With gussets and junction pieces of special form almost any combination can be effected.

The three remaining chapters are altogether of a practical character. In the fourth, wall ties, lintels, brackets, and bressumers are very fully dealt with and profusely illustrated. Chapter V. is devoted to the subjects of iron floors for railway stations, warehouses, theatres, stores, and private mansions, and the sixth and last treats of pillars and columns of cast, wrought iron, and steel of various sections, and of different methods of building up, including the twin columns and many ribbed base or bed plate. While simple and sufficient rules are given for calulation, it is not as a theoretical treatise that the volume of M. Denfer is to be regarded, but rather as a valuable collection of practical information, and numerous actual examples of constructive ironwork, useful alike to the student and professional man. The author reserves the subjects "Menuisirie et Serruririe" for the contents of the second volume.

---

*The Vale of Nantgwilt, a Submerged Valley.* Illustrative and descriptive of the Elan and Caerwen Valleys in Radnorshire, shortly to be submerged by the reservoirs for the water supply of Birmingham. By R. Eustace Tickell, A.M. Inst. C.E. London: J. S. Virtue and Co., 1894.

The object of this book is to preserve a record of one of the most charming valleys in Great Britain, scenes which are soon to be lost for ever, submerged beneath the waters of a chain of lakes, the reservoirs of the Corporation of Birmingham. The Vale of Nantgwilt lies at the junction of the rivers Elan and Caerwen on the borders of Radnor and Brecon. The united rivers flow into the Wye near the little market town of Rhayader. In this district 45,000 acres of land have been acquired by the Corporation of Birmingham for the purposes of its undertaking, and, when the works are completed, the valleys where now the rivers flow will be filled by a series of lakes, six in all. The sites of the Manor House of Nantgwilt, where Shelley settled in 1812 for a time, of Cwm Elan, which then belonged to his uncle, of two chapels, schoolhouse, and twenty farmsteads, will lie in depths varying from 40ft. to 90ft. of water.

More than thirty years ago the Elan Valley was selected as a suitable storage ground, and in 1871 Sir Robert Rawlinson reported upon it to the Corporation of Birmingham. Nothing came of this at the time, and in the autumn of 1890 the Corporation consulted Mr. Mansergh on the question of the extension of their water undertaking, who, after consideration of various schemes, advised the appropriation of the Elan site. Parliament gave its sanction in 1892.

Mr. Mansergh has contributed a chapter on the scheme to the work before us, from which we gather that under the powers of their Act the inhabitants of Birmingham may ultimately divert to themselves 73 million gallons a day. The aqueduct will have a length of 73 miles, with a fall of 170ft., delivering into a reservoir 600ft. above Ordnance Datum, in order that the whole district may be supplied by gravitation. The works authorised are intended to be carried out by instalments, the first of which, when completed, will be competent to supply 27 million gallons a day to Birmingham, and a like quantity of compensation water to the river. Mr. W. M. Rossetti contributes a chapter on Shelley at Cwm Elan and Nantgwilt, and probably no one is more competent for the task. The early history of the Manor is dealt with by Mr. Stephen W. Williams, F.S.A.

Besides a map of the district and a model of the watershed with some of the sections of the contemplated work, the book contains twelve full-page etchings from drawings made on the spot by Mr. Tickell himself. The greater part of the etching has been done by Mr. E. J. Burrow, of Cheltenham. The drawings are not all of the same standard of quality. Some subjects have been more congenial to Mr. Tickell than others. But they are all interesting and valuable, and some of them, in our opinion, show considerable artistic feeling and judgment. The plate "Dol-y-Mynach" is especially deserving of praise, the effect of sunlight and the distribution of masses being very pleasant. "Tan-y-Foel" and "Glan-yr-Avon" are also good. In "Pont-ar-Elan," and in a less degree "Cwm-Elan," Mr. Tickell has experienced and striven with the difficulty of rendering in black and white strongly illuminated surfaces of green. In his endeavour to reproduce the effect of light he has lost the advantage of colour, with the result that the pictures are rather snow-like. The plates are printed without affectation. There is no attempt at concealment or meretricious effect by *rétroussage*. The volume is interesting and attractive, and will no doubt be popular.

---

*Josiah Wedgwood, F.R.S.: His Personal History.* By Samuel Smiles, LL.D. London: John Murray. 1894.

We confess that our perusal of this book has resulted in some disappointment. It is now eight-and-twenty years since the publication of Miss Meteyard's "Life of Wedgwood," a work of long and laborious research, and which was generally accepted as exhaustive of the subject. It was, of course, more than possible that during the time which has elapsed since 1866, some further facts might have come to light, and the publication of Mr. Smiles's book naturally gave rise to the hope that he had struck new ground, and was in a position to tell us a good deal more than we already knew of Wedgwood and his work. This hope has, unfortunately, not been realised. Mr. Smiles tells us in his preface that he has had an opportunity of consulting the materials collected by Mr. Charles T. Gatty from the Wedgwood family manuscripts, which documents "for the most part had not been investigated by former biographers;" but Miss Meteyard—to whose work Mr. Smiles only refers in the most casual manner—acknowledges her obligation to the Wedgwood family and others, including Mr. Smiles himself, for the assistance they gave her. Mr. Smiles tells us that the papers include Wedgwood's diaries and commonplace books, his correspondence, invoices, &c.; but as he does not refer specifically to his authorities as he proceeds, we are left to our own resourses to discover what is the new matter of which he makes use. We have done our best, and we repeat that we are disappointed with the result. Some fresh documents are apparent, notably a few relating to Flaxman, one of which Mr. Smiles considers of great importance, as proving the authorship of the well-known bust of Mercury, but we were not aware that there ever was any doubt that Flaxman was the modeller. He has also found Sir William Hamilton's reply to Wedgwood's letter of June, 1786, to which Miss Meteyard confesses she has no clue. There are some further details of Wedgwood's journey to Cornwall in search of clay deposits, and here and there other new lights; but, upon the whole, we cannot say that the central personage or any of his contemporaries are made much better known to us, and, so far as we can find, we are told nothing new as to the potter's technology. In many places, as we read Mr. Smiles, we seem to be reading familiar passages from Miss Meteyard; but this may be due to the fact that both were working with the same materials before them. Mr. Smiles passes lightly over the vexed question of the mysterious Barberini or Portland vase. In one place he describes it as "perhaps the finest work of the kind made by the ancient Greeks;" in another he calls it "a splendid example of Greek or Etruscan art." But he does not deal with the suggestion of Alexandrian origin at all. Everything from the pen of Mr. Smiles is read with so much interest that criticism is inevitable, and probably invited; but, notwithstanding shortcomings, there is no doubt that within the compass of this little volume the author has presented us with a just and very readable biography of a most interesting person.

---

*Transportation Exhibits at the Columbian Exhibition,* 1893 By James Dredge. London: Office of *Engineering*, Bedford-street. New York: James Wyley and Sons. 1894.

This is a colossal folio, beautifully printed on excellent paper, and copiously illustrated. We are somewhat at a loss to imagine how one busy man could, in a very few months, produce such a work. The title is, moreover, in some sense a misnomer, because the book treats of multitudinous matters which have only a remote connection with transportation. Thus, for example, stationary engines and electric lighting plant are not necessarily connected with transport; and this is also true of guns—unless, indeed, we regard them as means of transporting projectiles from place to place in a hurry.

Mainly, however, the volume is devoted to rolling stock and steamships. The American locomotive has never been more fully described and illustrated in all its types and varieties. Everything in the book has been well done, and the result is, as a whole, in this sense quite satisfactory. But the work has a defect which will militate against its utility. It is quite too unwieldy. Had it been divided into two volumes, each would still have been too large. By far the better arrangement would have consisted in treating each subject to itself. As a record the book will be in the future invaluable. Its utility in the present is as a work of reference, and for that it is too unhandy. The age of ponderous tomes has passed away, and our appreciation of Mr. Dredge's book is tempered by the reflection that it is a survival of an all but extinct type. It can, however, fairly claim that it is the finest record of a great exhibition that has ever been published.

---

### BOOKS RECEIVED.

*Tempera e Cementazione per l'Ingegnere Starnislo Fadda.* Milano, Ulrico Hoepli. Editore-Libraio della Real Casa. 1894.

*The Elementary Properties of the Elliptic Functions.* With examples. By Alfred Cardew Dixon, M.A. Price 5s. London: Macmillan and Co. 1894.

*An Elementary Treatise on Theoretical Mechanics.* By Alexander Ziwet. Part III.: Kinetics. Price 8s. 6d., net. London: Macmillan and Co. 1894.

*Eleventh Annual Report of the Bureau of Ethnology to the Secretary of the Smithsonian Institution,* 1889-90. By J. W. Powell, Director. Washington Government Printing Office. 1894.

*Tenth Annual Report of the Bureau of Ethnology to the Secretary of the Smithsonian Institution,* 1888-89. By J. W. Powell, Director. Washington: Government Printing Office. 1893.

*Elliptical Orbits: Their Distinctive Mechanical Characteristics and their Possible Origin.* By Henry Larkin. With original illustrations. Price 1s. London: T. Fisher Unwin. 1895.

*Twelfth Annual Report of the United States Geological Survey to the Secretary of the Interior,* 1890-91. By J. W. Powell, Director. Part I., Geology. Part II., Irrigation. Washington Government Printing Office. 1891.

*A Treatise on Industrial Photometry, with special application to Electric Lighting.* By A. Palaz, Sc.D. Authorised translation from the French by George W. Patterson, jun., M.A.B.S., and Merib Rowley Patterson, B.A. London: Sampson Low, Marston and Co. 1894.

*Provisional Orders of the Board of Trade in reference to Gas and Water, Tramway, Pier, and Harbour, and Electric Light Undertakings, being a Manual of Practice for Promoters, Opponents, and others.* By Francis J. Crowther. Second edition. London: Jordan and Sons. 1894.

*The Railway Diary and Officials' Directory,* 1895, *and The Railway Almanack.* London: McCorquodale and Co., Limited, and W. H. Smith and Son. The almanack is a very useful sheet of information, relating to our railways and railway traffic and officials, and the diary maintains the high character it has earned as a most useful reference book on railway matters.

*History of the Tower Bridge and of other Bridges over the Thames built by the Corporation of London.* Including an account of the Bridge House Trust from the Twelfth Century, based on the records of the Bridge House Estates Committee. By Charles Welch, F.S.A.; with a description of the Tower Bridge by J. Wolfe Barry, C.B., M. Inst. C.E., and an introduction by the Rev. Canon Benham, B.D., F.S.A. Prepared under the direction of the Bridge House Estates Committee—Sir Albert J. Altman, chairman. London: Smith, Elder and Co. 1894. 25s. net.

*Hazell's Annual for* 1895: *A Cyclopædic Record of Men and Topics of the Day.* Edited by W. Palmer, B.A. (Lond.). Revised to November 26th, 1894. Tenth year of issue. London: Hazell, Watson, & Viney, Limited. Hodder and Stoughton. 1895. Among the new articles written specially for this edition, we notice those on astronomy, bullet-proof cuirasses, electricity, engineering inventions during the year 1894, mining and railways, all of which are terse and well worth reading—giving, as they do, leading dates, figures, and facts connected with these subjects. Apart from this, the "Annual" is a valuable book of reference and fund of information to all who wish their general knowledge to be up to date.

*Toothed Gearing: A Practical Book for Offices and Workshops.* By a Foreman Patternmaker. London: Crosby Lockwood and Sons. *Helical Gears: A Practical Treatise.* By a Foreman Patternmaker. London: Whittaker and Co. These are practical and useful books, and though written a good deal from the pattern-making point of view, which is most important in connection with gearing, they show that the author's knowledge would enable him to describe himself by several other titles. The book on helical gears, how to design and mould them, was necessary, and will be found a useful guide in the office and workshop. We notice that, like other authors on gearing, he omits to deal with internal toothed gear.

*Forty-three Graphic Tables and Diagrams for the Conversion of Measurements in Different Units.* By Robert H. Smith, Professor of Engineering, Mason College, Birmingham. Price 7s. 6d. London: Charles Griffin and Co. 1895—The tables are intended to show at a glance the figures which correspond in one system with their values in another in questions relating to length, area, volume, weight, stress, density, work, and energy in mechanical, thermal, and electrical units, horse-power, and temperature. These tables are very useful for showing at a glance figures which would take much longer time to obtain in other ways. One of the horse-power tables, for instance, gives at a glance English and French horse-power, and English or French horse-power compared with kilowatts.

*Turning Lathes: A Manual for Technical Schools and Apprentices; a Guide to Turning, Screw Cutting, Metal Spinning, Ornamental Turning, &c.* With 225 Illustrations. Edited by James Lukin, B.A. Fourth edition. Britannia Company, Colchester.—The additions to this edition form a most interesting as well as a large part of the book. They deal particularly with the use of excentric, oval, and dome chucks and the horizontal cutting frame, all of which are so useful in the ornamental turning in which amateurs delight. Some additions, however, relate to important work in connection with pattern-making and with the turning of various shapes required in instrument and other construction. The engravings of this edition are an improvement on those of the first edition.

*The London Building Act,* 1894. *With Bye-laws and Regulations of the London County Council, and Introduction, Notes, Cases, and Index.* By Alex. J. David, B.A., LL. M. (Cantab.), of the Inner Temple, barrister-at-law. Price 3s. 6d. London: Crosby Lockwood and Son. 1894.—This book sets forth and explains the new Act which comes into force on the 1st of January, 1895. It consolidates all the existing enactments, and places them under a single Act. Its importance is shown by the fact that no less than three papers are about to be or are now under discussion before the Architectural and Sanitary Engineering Societies. Cases forming precedents in each section are given throughout the book. It may be hoped that some of the inconsistencies and useless restrictions common under the existing Acts will not be possible under the new one.

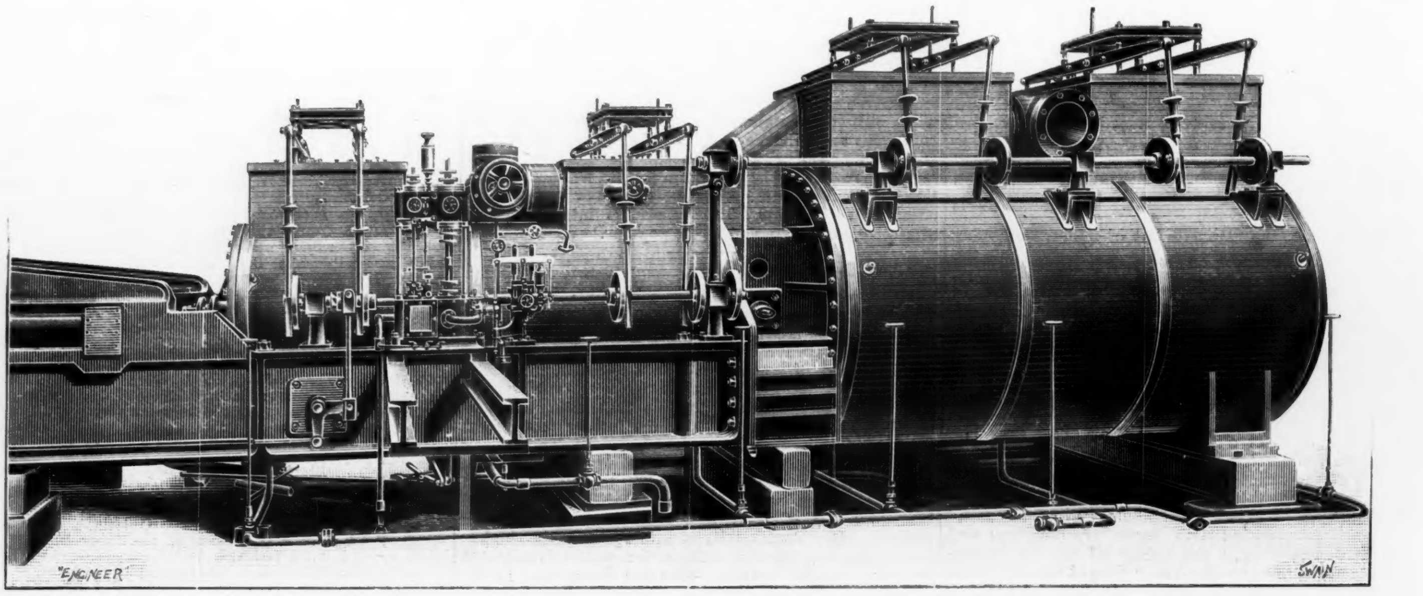
*The "Fifty-One Hour" Wages Reckoner.* Consisting of computations per week and computations per hour for a working month, with a supplementary comparative table, applicable to weeks of forty-eight, fifty-four, fifty-seven, and sixty hours respectively. By a Retired Banker. Price 2s. 6d. Edinburgh: Johnstone, Hunter, and Co. 1894.—These tables give the wages for any number of hours and parts of hours, from one hour to fifty-one, and at wages varying from 2s. to £2 10s. per week of fifty-one hours. The tables occupy 244 pages, and extend from the quarter of an hour to 231 hours or twenty-seven working days, so that they suit for monthly payments. A supplementary table is given, which shows the value of one hour's labour contained in the fifty-one hours' table as compared with the value when the hours are forty-eight, fifty-four, fifty-seven, or sixty per week.

---

On Tuesday last the Metal Trade Section of the London Chamber of Commerce met to consider the desirability of recommending the Council of the Chamber to take steps with a view to preventing the unfair competition of insolvent companies for Government work by urging the insertion of a clause in all Admiralty contracts for chains, cables, anchors, &c., similar to that which is inserted in the conditions of contract of the War-office, India-office, and Trinity House, *i.e.*—That should the contractor be adjudged bankrupt or have a receiving order made against him, or make or enter into any arrangement or composition with his creditors, or suspend payment, or being a company, should enter into any liquidation, compulsory or voluntary, the contract may be determined summarily by the Lords Commissioners of the Admiralty without compensation to the contractors.

# ONE THOUSAND HORSE-POWER PUMPING ENGINES

MESSRS. HATHORN DAVEY AND CO., LEEDS, ENGINEERS

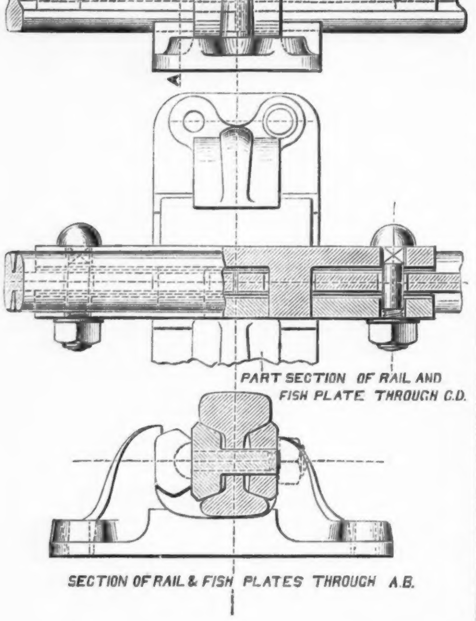


## DAVEY PUMPING ENGINE.

We illustrate a pair of Davey pumping engines of large size recently made by Messrs. Hathorn, Davey, and Co., of Leeds, for draining mines. Three pairs were made from the same designs—two pairs were sent abroad, and one pair to South Wales. The pair of engines are erected side by side and pump from the same pit, both engines and pumps being duplicates of each other. Together they represent 1000-horse power in water lifted. The cylinders are 40in. and 76in. by 10ft. stroke. In one case the pumps are placed at the bottom of the pit 800ft. from the surface, the connection between the engine and the pumps being made with spur rods 20in. square of pitch pine. This system—which was originated, and has been developed by Mr. Davey—of pumping to great heights in one lift with spear pumps, is now very largely employed. The old system was to divide the depth into lifts not exceeding 250ft., one pump lifting to the next one above it. These pumping plants are very heavy, one pair of the engines which we illustrate, with its pumps complete, weighing upwards of 1000 tons. The valve gear is a modification of the well-known differential gear. If a breakdown takes place, steam is immediately and completely shut off.

## PITTWAY AND WOOD'S FISH-PLATE.

The fish-plate illustrated by the engravings below is and has been under trial on the Manchester, Sheffield, and Lincolnshire Railway under heavy mineral traffic, which they have, we are informed, now carried for over nine months.



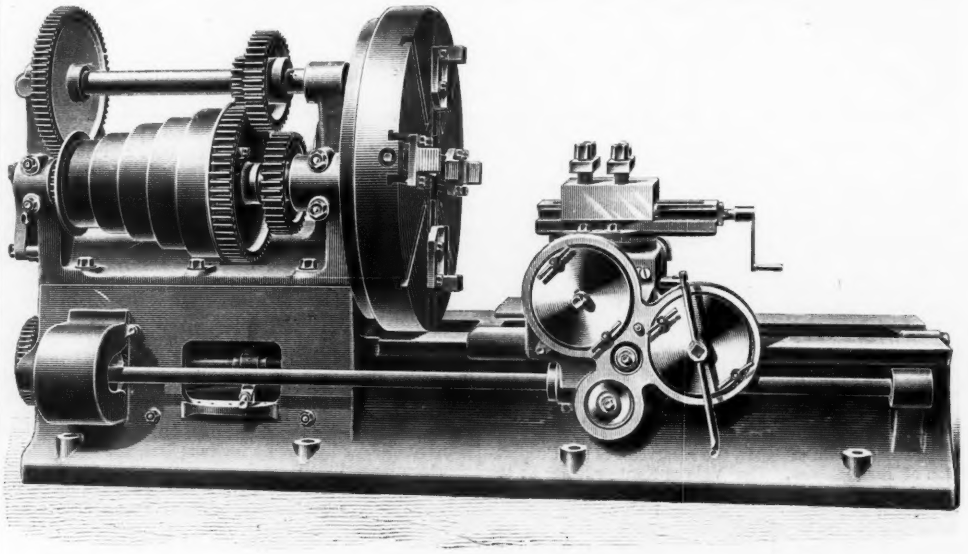
PART SECTION OF RAIL AND FISH PLATE THROUGH C.D.

SECTION OF RAIL & FISH PLATES THROUGH A.B.

The claims made for the new fish-plate are, that while it supports the rails where they butt, a chair may be placed under the fish-plate, which cannot be satisfactorily done with those now generally in use. Further, the spigot being part of the fish-plate, and going through the rails, keeps both ends level, and thus prevents the wearing of the ends of the rails, and the harmful hammering which consequently takes place at these joints. They are made by Mr. W. O. Wood, of Anerley, London.

## SURFACING AND BORING LATHE.

We herewith illustrate a surfacing and boring lathe, arranged to produce chuck work rapidly. It possesses features which, though not novel in principle, are sufficiently so in application to deserve notice. The feeds, which are positive and continuous, admit of change by movement of a handle in front of the headstock, without stopping the lathe, the alterations taking place almost instantaneously. The feed can also be started or stopped by means of the thumbscrews, shown on discs. The principal dimensions of this lathe, which weighs 110 cwt., are as follows:—Height of centre from bed 24in., swing 48in., chuck 45in. diameter. The makers are Messrs. John Lang and Sons, Johnstone, N.B.



SURFACING AND BORING LATHE

## GRAVITATION WATER SUPPLIES AND ELECTRIC ENERGY.

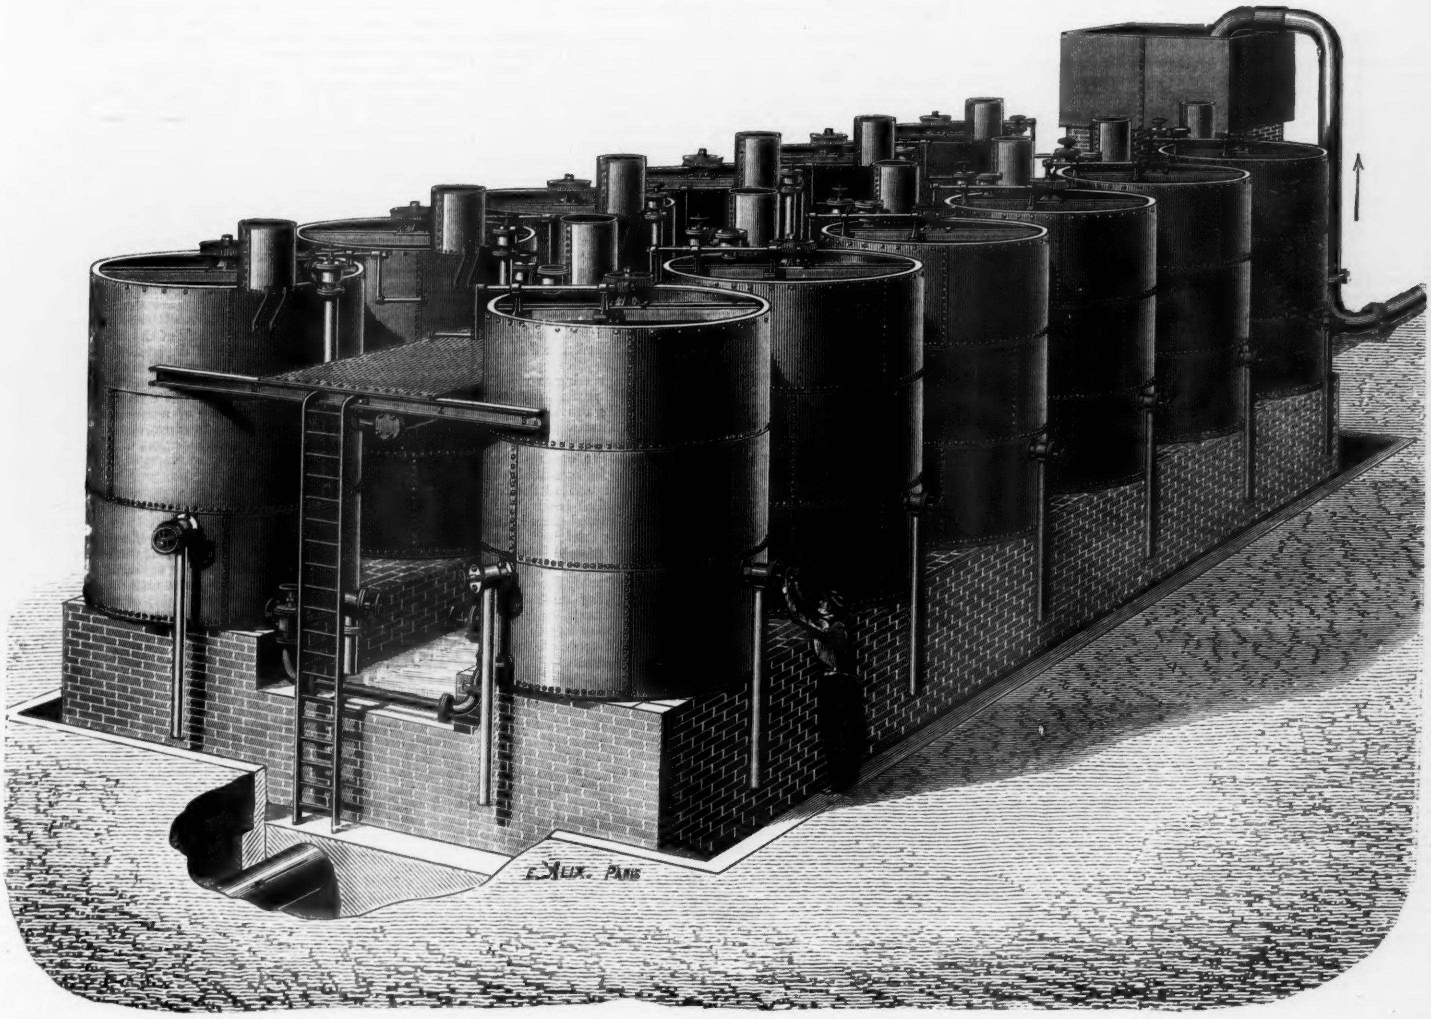
The rapidly extending use of water power for the generation of electricity at many places abroad has naturally directed attention to the home possibilities in this direction. These are soon found to be disappointing, the best water power locations having been long ago utilised for various motive purposes. There are, it is true, numberless points on the smaller streams throughout the country capable of furnishing power for small lighting installations; but generally the water power in Great Britain, not subject to old established rights, is meagre or capricious. In some parts of Ireland, however, there is abundance of water power capable of utilisation. But apart from natural sources, there is another and constantly increasing form of water power in the great works, completed and in progress, for supplying the inhabitants of cities, towns, and villages, with potable water. Here also, however, a very slight amount of investigation shows that though the power represented in many cases by the flow of water and its fall may be great, the energy capable of utilisation is generally small, and often practically non-existent. For instance, at Glasgow nearly 50,000,000 gallons of water flow daily into the city and suburbs from Loch Katrine, which has an elevation of about 350ft. above the lower streets of the town. The power represented by these figures would, if capable of employment for lighting by electricity, effect a great saving in the corporation coal bill. But, of course, the water does not run direct from the highest to the lowest point. It runs first into the distributing reservoirs at Craigmaddie, situated some 50ft. below the level of Loch Katrine, and is conveyed mainly in open culverts, so that little power is derivable at its debouchment. From Craigmaddie the water is piped; but some of the natural elevations in Glasgow are over 250ft. in height, with buildings of about 50ft. elevation on their summits; so that in some cases the head of water does not suffice for the supply, and pumping is resorted to. In short, though in some of the lower districts there may be at times an excess of pressure, practically all the energy due to the head and volume of water is absorbed in its own distribution. Very similar conditions obtain in cities like Manchester and Liverpool. There are, however—especially in Scotland—many towns where the gravitation water supplies are capable of furnishing considerable quantities of electrical energy at a comparatively small outlay and without detriment to the water distribution. To cite a case—a small town on Clyde, with reservoirs at over 500ft. above the river level, gives its inhabitants a liberal supply of 600,000 gallons per day. To keep the pressure at the lower parts of the town within reasonable limits, the main pipe is broken 250ft. below the level of the reservoirs, the water discharging into a distributing tank with an amount of energy equal to nearly one hundred horse-power—in the meantime unutilised. To have undertaken the construction of the works merely to get this power would have been out of the question; but the instance shows that it may be quite worth the attention of engineers, when laying out new works in hilly districts, to consider the power possibilities of their schemes, as there are no doubt many localities adapted for the combination of a power station and water supply works.

Naval Engineer Appointments.—The following appointments have been made at the Admiralty:—Engineers, George W. Roome, to Royal Naval College; G. E. Wheatley, to the Cockatrice. Assistant Engineer, J. W. Mountifield, to the Blenheim. Probationary Assistant Engineer, Charles J. M. Wallace, to the Hood.

Patents in Japan.—The following is an extract from a letter concerning patents and trade marks in Japan, which has been received by Mr. J. E. Evans-Jackson:—"A new treaty has been concluded with Japan. Article 17 of the treaty provides that 'the subjects of each of the high contracting parties shall enjoy in the dominions and possessions of the other the same protection as native subjects in regard to patents, trade-marks, and designs, upon fulfilment of the formalities prescribed by law." By a proctocol signed at the same time, and which, together with the treaty, will shortly be published, the Japanese Government undertake before the cessation of British Consular jurisdiction in Japan, to join the international conventions for the protection of industrial property and copyright. The treaty will, however, not come into force for at last five years, and, until it does, British Consular jurisdiction in Japan will continue to be exercised.

# BATTERY OF FILTERS, LAY SUGAR FACTORY, CAIRO

MESSRS. THWAITES BROS., BRADFORD, ENGINEERS



## FILTRATION OF NILE WATER FOR SUGAR WORKS.

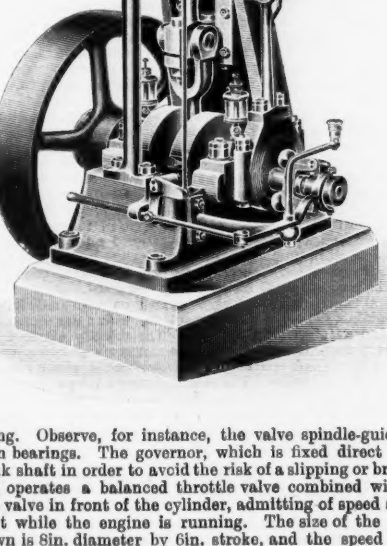
The above illustration is from a photograph of a battery of filters lately erected at the "Lay Sugar Refinery," Cairo. The plant was erected for the purpose of filtering water drawn from the river Nile, which brings down large quantities of mineral and organic matter in suspension, all of which must be removed. Each of these filters is 9ft. diameter by 11ft. high, and is, we are informed, capable of passing 220,000 gallons per 24 hours, giving a total output for the whole battery of over 2½ million gallons per 24 hours. The filters, the essential features of the construction of which we described in our impression for January 4th last, are so arranged that the cleansing of each filter bed can be easily and rapidly effected by causing filtered water to flow upwards through the bed, which is composed of 2ft. of specially prepared and graded crushed silex; and by the simultaneous use of the circular rake or agitator, with which each filter is fitted, and worked from the gangway by means of a crank handle and worm and wheel gearing. The small tank at the top of each filter is to hold a solution of sulphate of aluminium or some similar material, which is allowed to drop into the filter, and by reason of its properties of coagulation is able to assist the filter bed in its work. The whole of this precipitant or coagulant is caught in the bed, and its presence cannot be detected in the filtered water. The rate at which these filters do their work of separation and filtration is remarkable. The aggregate area of the twelve filter beds is 763·44 square feet, through which the water passes at an approximate speed of 23ft. per hour, giving a duty of 144 gallons per square foot per hour. These filters have, we are informed, proved most successful where it has been necessary to remove matter in suspension from organically pure water, or from water which is to be organically purified by a secondary and slower filtration through some oxidising medium, such as "Polarite," the virtue of which would be to a large extent destroyed were it allowed io become clogged by suspended matter. The filters are made under Howatson's patents by Thwaites Bros., Ld., Bradford.

---

Dock Pumping by Gas Engines.—Messrs. Crossley Brothers, Limited, of Manchester, have secured an important contract for the River Wear Commissioners at Sunderland. The work is in connection with a large graving dock. It consists of discharging 14,800 tons of water in two hours. Three of Messrs. Crossley Brothers' new patent scavenging engines will be used, coupled direct to three large centrifugal pumps, made by Messrs. Gwynne and Co., of Brooke-street Works, Holborn. A smaller engine and centrifugal pump is also to be used for keeping down the leakage water after the dock is emptied. The whole arrangement has been carefully thought out under the direction of Mr. H. H. Wake, C.E., the Commissioners' engineer; and as this is a new departure in direct gas engine driving with centrifugal pumps, the results may be looked forward to with considerable interest. When completed it will be the largest gas engine pumping plant in the country. The great advantage in using gas engines for this purpose is that the power is available as soon as wanted, and there is no occasion to keep steam up all day on the offchance of the engines being required. We may add that the ordinary town's gas is being used in this instance for driving the engines.

## HIGH SPEED ENGINE.

The illustration shows a high-speed engine suitable for coupling direct to dynamos, although it can be used for belt driving besides. The back column and sole-plate are cast together, and the general design of the engine is unusually strong. Observe, for instance, the valve spindle-guide and main bearings. The governor, which is fixed direct to the crank shaft in order to avoid the risk of a slipping or breaking belt, operates a balanced throttle valve combined with the stop valve in front of the cylinder, admitting of speed adjustment while the engine is running. The size of the engine shown is 8in. diameter by 6in. stroke, and the speed is 325 revolutions per minute. These engines are made in various sizes by Alex. Shanks and Son, Limited, of 110, Cannon-street, E.C., and Arbroath.



---

The Civil and Mechanical Engineers' Society.—On Wednesday week a large number of members of this Society visited the works of the East London Water Company at Lea Bridge, and were kindly shown over, by the Chief Engineer, Mr. W. B. Bryan, M.I.C.E., the various engine-houses, turbine-houses, and other works of this ancient water company. The members inspected four Cornish pumping engines, three sets of triple expansion Corliss gear engines, and a new set of triple expansion overhead marine type pumping engines, two compound horizontal pumping engines, and four Hercules turbines used for pumping. The members were also shown a rotary pump made by the Drum Engineering Co., working under a head of 200ft., which had been tested, and was stated to have yielded an efficiency of 80 per cent.; many and various apparatus for facilitating communication between districts; the working and governing of the engines and pumps, amongst these being notably that of the electrically-worked stop valve, and many ingenious contrivances designed by Mr. W. B. Bryan. The members were also shown over the new boiler-house, inspected the sluices, the tubular aqueduct over the canal, and had a very interesting description, given to them by the engineer, of the working arrangements of the company, the difficulties met with and overcome in obtaining water from their wells; and also were shown some of the original receipts of Messrs. Bolton and Watt for money paid to them at the end of last century for coal saved by those pumping engines that had been erected by them. Among those present were Messrs. C. T. Walrond, C.E. (the President), R. Booth, C.E., Rowan, C.E., Kuhne, C.E., E. H. G. Brewster, C.E. (hon. sec.), A. Wollheim, C.E., J. F. Reade, C.E., W. M. Binny, C.E.

Institution of Civil Engineers: Manchester Association of Students.—A meeting of this society was held on the 12th, when Mr. C. H. Wordingham, Assoc. M. Inst. C.E., read a paper describing the Manchester Electric Lighting Works. Mr. A Ross, M. Inst. of C.E., President of the Association, occupied the chair. The author first referred to the interest excited among engineers by the Manchester electric supply on account of its magnitude and importance, and more especially because the five-wire system decided upon by the engineer, Dr. John Hopkinson, F.R.S., M. Inst. C.E., is entirely new in this country, and has not been largely used either in Europe or America. He stated that after rather more than a year's working Dr. Hopkinson's boldness has been fully justified, and it is interesting to note that the St. Pancras Vestry are on the point of converting their three-wire into a five-wire system. He then described in detail the arrangement of the fire-wire system and the method of working the same, comparing the method and arrangement of the two and three-wire systems. He next explained the system of mains and the method of running the conductors and the switching arrangements, passing on to a description of the dynamos, engines, boilers, and coaling arrangements. The author stated that up to date 55,700 incandescent lamps, reckoned in the equivalent of 8-candle power each, 311 arc lamps and eleven motors, have been connected to the mains, and that the number of applications at present is very large. Considerable extensions are contemplated for next winter, and there is every indication that this will be the largest municipal station in the kingdom. Messrs. J. W. Welch, J. F. Conradi, H. M. Allott, and A. J. Jenkins took part in the discussion which followed, and a hearty vote of thanks was passed to Mr. Wordingham for his interesting paper, on the motion of Mr. Allott seconded by Mr. Parkinson.

# LEGAL INTELLIGENCE.

## SUPREME COURT OF JUSTICE.—COURT OF APPEAL.

(*Before the* Master of the Rolls, Lord Justice Lopes, *and* Lord Justice Rigby.)

December 18th, 1894.

### MUIRHEAD AND OTHERS V. COMMERCIAL CABLE COMPANY.

This was an appeal of the defendants from the judgment of Mr. Justice Kennedy at the trial of the action without a jury, a report of which, with the judgment, was given in The Engineer of the 4th of May last. The plaintiffs, who are the patentees and proprietors of certain patents for the system of duplicating cables known as the Muirhead duplex system of telegraphy, sued the defendants, a foreign company, incorporated under the laws of the United States of America, and the owners of certain telegraph cables between North America and Ireland, to recover £356 for royalties in respect of a part of the year 1891, under a deed dated January 2nd, 1884, giving the defendants a licence to use certain patents of the plaintiffs in consideration of certain yearly payments. The defendants admitted the deed, but alleged that the patents in question had expired at a certain date, and that they were not liable to pay the royalties claimed. As set forth in our impression above referred to, that Messrs. Muirhead took out an English patent in 1876 for duplex telegraphy, and in 1880 they took out a patent in the United States for duplex telegraphy. The English patent expired in 1890, and the defendants contended that the American patent of 1880 was substantially identical with the English patent of 1876, and that the American patent expired at the same date as the English patent, inasmuch as the law of the United States provides that every patent granted for an invention which has been previously patented in a foreign country shall be so limited as to expire at the same time with the foreign patent. They, therefore, contended that the American patent had expired, and that they were not liable to pay the royalties claimed. If, on the other hand, as the plaintiffs contended, the American patent were not substantially identical with the English patent, the American patent would last for seventeen years from 1880, and the defendants would, therefore, be liable not only in this action, but also for royalties up to the expiration of the American patent. It appeared that by means of Muirhead's duplex system of telegraphy two submarine telegraphic messages could be sent along the same cable at the same moment in opposite directions. Formerly, when a message was sent along the cable from, say, England to America, the receiving instrument on the English side as well as that on the American side was affected by the electric current. Muirhead's patents were to render the receiving instrument at the end from which the message was sent unaffected by a message sent from that end, with the result that a message could be sent from the opposite end at the same time. The chief essential was to maintain a perfect balance of electrical pressure, and this was done by means of a mechanical contrivance, used at both ends of the cable and known as Muirhead's artificial cable, in combination with certain resistances and other known electrical appliances. At the trial a large number of scientific witnesses were called upon both sides as to whether the two patents were substantially identical—that is, whether the two inventions claimed were the same. The learned Judge came to the conclusion that the English patent of 1876 did not contain the same combination as was found in the American patent of 1880, and that the latter was a good and novel patent. He accordingly gave judgment for the plaintiffs. The defendants appealed.

Sir Richard Webster, Q C., and Mr. Moulton, Q.C.—Mr. A. J. Walter with them—appeared for the defendants; Mr. Finlay, Q.C., and Mr. Bousfield, Q C.—Mr. Pollard with them—appeared for the plaintiffs.

The Court, having taken time to consider, delivered judgment on Tuesday last, allowing the appeal, the Master of the Rolls dissenting.

The Master of the Rolls said that the question in the action related to two patents, one in England and the other in America. If the American patent had not expired the plaintiffs were entitled to recover. The case was tried before Mr. Justice Kennedy, and he (the Master of the Rolls) was prepared to say that he had never read a judgment more accurately written, in which the learned Judge went step by step through the case most carefully, and the judgment was so admirably expressed that he was unable now to add anything to it, and he was prepared to adopt it as his own. The learned Judge stated the law correctly, and the question was whether the invention patented in America was the same invention as was patented in England. The patent in America was for a combination. It was so in terms, and was so claimed. That combination consisted in the relative position of certain things in it which were to do the work, and the patent was for a combination of those things in that position. Then how could the English invention be the same unless it was for the same combination? The English invention was not claimed as a combination, nor was it used as a combination. Certain of the scientific witnesses stated that the particular placing of the things as described in the American patent was a most useful invention, and that between the time of the English and the American patents the combination was not used because it was not discovered. Therefore, he came to the conclusion that the American patent was not the same as the English patent. He came to the conclusion that Mr. Justice Kennedy was right. But if the matter was left in any doubt, in order to shorten the period of the American patent the whole burden of proof rested on the defendants, and, the matter being left in doubt, that burden had not been discharged. In his opinion the appeal should be dismissed.

Lord Justice Rigby read the judgment of Lord Justice Lopes and himself, in the course of which he said that the decision in the case depended upon one point, and one point only—namely, whether or not the United States patent of 1880 came to an end when the English patent of 1876 expired. He did not think that Mr. Justice Kennedy's findings as to the United States law could be impeached, and he agreed with the learned Judge that a test of the identity of the patents was whether a structure made according to the foreign patent would infringe the United States patent. He also agreed that the burden of proving the identity of the two inventions lay upon the defendants, and that the principle of introducing into any patent by implication any claim not expressly contained therein, ought to be applied with the greatest possible caution. His Lordship then proceeded to consider the construction of the two patents and the evidence relating thereto, and, having elaborately examined the two patents and having gone through the scientific evidence upon the point, came to the conclusion that the defendants had made out their case affirmatively, and that there was no room for the application of the principle that, where there was a doubt, the doubt should be resolved in favour of the United States patentee. He did not in any way differ upon the law from the learned Judge, whose judgment, he agreed, was most admirably expressed, but he did differ rom him in the conclusions of fact at which he had arrived.

---

*Before* Lord Halsbury *and* Lords Justices Lindley *and* A. L. Smith.)

### HELFER *v.* THE CITY OF LONDON ELECTRIC LIGHTING COMPANY—MEUX'S BREWERY COMPANY (LIMITED) *v.* THE SAME.

These appeals were against a decision in April last by Mr. Justice Kekewich refusing an injunction to restrain the City of London Electric Company from causing a nuisance by noise and vibration resulting from the running of their engines and generating machinery. Their Lordships reversed the decision of Mr. Justice Kekewich, and decided that the injunction must be granted.

# REPORT OF THE SECRETARY OF THE UNITED STATES NAVY.

The annual report of Mr. Herbert, Secretary of the Navy of the United States, was issued in November, and the following are some extracts therefrom :—

The following new vessels have been completed and tried since the date of my last report :—Marblehead, 18 44 knots ; Columbia, 22·80 knots ; Olympia, 21·69 knots ; Montgomery, 19,056 knots ; Minneapolis, 23·076 knots. The Indiana, Texas, and Oregon have had unofficial preliminary trials under the direction of the contractors, and the Maine had her official machinery trial on October 17th, 1894, her engines developing 9224·3 indicated horse-power for four hours, and showing an average speed of 17 knots.

The last Naval Appropriation Act contained a provision authorising the construction of three additional torpedo-boats. The department has carefully considered questions relating to the development of this type of vessel, both at home and abroad, and has finally decided upon the construction of torpedo-boats of the general type of the Ericsson, and with a slightly greater displacement, and to attain an average speed of not less than 24·5 knots on the acceptance trial. No speed premiums will be provided for in the contracts for the building of these vessels. In the contracts for the construction of gunboats Nos. 7, 8, and 9 small premiums and penalties were provided for. This system undoubtedly has its advantages when adopted, but reflection has convinced the department that the time has come when with the experience that has been gained by it may with profit be abandoned.

Work on the first-class battleship Iowa is progressing as rapidly as the requirements of good workmanship will permit, and it is expected that the vessel will be completed during the latter part of 1896. The first-class battleships Indiana, Massachusetts, and Oregon are well advanced toward completion, and will be in condition for acceptance by the Government within the coming year. The second-class battleship Maine will be ready for commissioning before the end of this fiscal year. She is being built at the New York naval yard, and her recent machinery trial at sea indicates that she is to be a gratifying success. The second-class battleship Texas is practically ready for her machinery trial, and should be completed and ready for commissioning a few months later.

Work on the armoured cruiser Brooklyn is progressing favourably, and it is expected that this vessel will be completed during the early months of 1896. Rapid progress is being made on the double-turreted monitors Puritan and Monadnock, and these vessels will probably be ready for trial before the end of this fiscal year. Work on the double-turreted monitors Terror and Amphitrite is so well advanced that, in case of an emergency, these vessels could be prepared for service within a few months. The armoured ram Katahdin will probably be completed during the early part of the next fiscal year. The protected cruiser Olympia has been successfully tried, and is now practically ready for commissioning. The progress of work on the three gunboats Nos. 7, 8, and 9 is such as to indicate that they will be completed within the contract time. Such an examination as the department has been able to make, with the information at its disposal, appears to justify the conclusion that these vessels have been contracted for at a price per ton fully as low as is paid for similar work in France and England.

Shortly before my last annual report was submitted, the department discovered that the Detroit and her sister ships, the Montgomery and Marblehead, and the Machias and her sister ship, the Castine, all then nearing completion, were deficient in initial stability. In order to obtain positive and accurate knowledge, a board, of which Rear-Admiral J. G. Walker, United States Navy, was president, and consisting of officers who had been in nowise connected with the designing or construction of these ships, was appointed to thoroughly examine these ships, and make such recommendations as might be deemed necessary. The changes recommended in the three ships of the Detroit class have been made, and these vessels are now fully equal to the exigencies of the naval service, and are in commission. The board recommended removing certain top weights from the Machias and Castine, placing ballast in their bottoms, and lengthening each of them by 14ft. This has also been done, and the result of the alterations has justified the wisdom of the recommendations. The discovery of the errors in the construction of the two last-mentioned ships induced the department to extend the functions of the Walker Board, and to order a thorough examination of all vessels then in process of construction about whose stability there could be any possible question. If errors existed in the designs of these other ships, it was important that the department should have knowledge of them at the very earliest moment. The report of the board was highly satisfactory, and especially as to the battleships, the board reporting that "The result of the inclining experiment of the calculations of these vessels is a most satisfactory and gratifying verification of the results of the original design, demonstrating a remarkable degree of accuracy in the calculations." The difference between the estimates and the actual result was five-eighths of an inch less metacentric height than design.

The guns required for the new vessels heretofore authorised are now so nearly completed that the construction of a sufficient reserve supply should be begun without delay, and the department recommends an appropriation to that end. Congress should give careful attention to the ordnance requirements of vessels that are liable to be called into service as auxiliaries in time of war, in accordance with the Acts of Congress approved March 3, 1891, and May 10, 1892, providing that steamers registered under the provisions of said Acts can be used by the United States as transports or cruisers. To mention no others, the Paris and New York, of the Inman Line, are now receiving large sums of money annually on condition that they hold themselves in readiness to serve the Government whenever demanded. When they hauled down the English to hoist the American flag they were receiving pay from the British Government to hold themselves in readiness to serve that nation, and the English had guns and gun-mounts ready to be put upon them at a moment's notice. We have now been paying subsidies to these ships for months, and have not a gun to put upon them.

With the exception of common shells for 13in. guns, the number of projectiles already ordered will suffice to complete the outfits of all ships thus far authorised. The higher development of armour-piercing projectiles, necessitated by the advent of hard-faced armour, is being carefully sought after, and all possible encouragement has been given to projectile makers. Of the different types already experimented with, some cast steel projectiles of large calibre made by J. G. Johnson and Co. have given very satisfactory results, such as to indicate that as good a projectile can be made of cast steel, properly treated, as has yet been produced by forging. If subsequent experiment should bear out this conclusion, the cost of projectiles will be materially decreased.

Practical experiments have been carried on with an 80 lb. 6 in. shell, containing 11 lb. of wet gun-cotton, with a dry gun-cotton primer and a fulminate detonator. The velocity attained was about 1400 foot-seconds, while at the maximum elevation usually attainable from ship's sponsons or turrets, would give a range of not less than three miles. The results obtained were so favourable as to lead to continuing the experiments with a 10in. shell containing about 70 lb. of gun-cotton, and fired with a charge giving an initial velocity of about 1700 foot-seconds, sufficient at the maximum elevation attainable from closed turrets, to give a range of over four miles.

As was stated in my last report, this department adopted a calibre of 6 mm. (0 236) for the new Navy rifle. During the last year exhaustive experiments have been conducted with a view to the determination of the length and metal of barrel, the most suitable powder charge, and all the other essential features of the modern rifle, these conditions to be observed in competitive trials which the department has decided to conduct prior to adopting a type of small arm for the Navy. In the experimental firings with the new rifle, muzzle velocities of about 2,900 foot-seconds were attained; but a charge of 36 grains was finally fixed upon in order to keep the chamber pressure well within a safe limit, and also to increase the lifetime of the rifle barrels. This charge gives a muzzle velocity of 2500 foot-seconds. With this velocity the point blank range is about 700 yards, and the effective range fully 4000 yards. At short range the penetration is about 5ft. of pine wood. The enormous increase of effectiveness over the old-fashioned rifle is apparent from these figures.

After the date of my last report, exhaustive practical experiments were conducted to determine the effect upon the crew of a submerged boat of the detonation near by of a high explosive under water. These experiments were carried on at the Naval Torpedo Station, at Newport, R.I., by exploding gun-cotton charges at various distances from a submerged structure containing living animals. An old Lay torpedo, about 28ft. long, was submerged 15ft., and 80 lb. charges—dry weight—of gun cotton moored at the same depth were detonated at the following distances from it :—400ft., 305ft., 200ft., 150ft., 100ft., and 80ft. The first experiment resulted in sinking the boat, drowning the contained animals; but it was found on raising that no injury had been done to the boat by the explosion beyond opening the seams, causing leakage with resultant sinking, and after slight repairs the other experiments were carried out, the boat being raised after each explosion and the animals examined. It was not until the 80ft. distance was reached that there was any signs of injury to the hull of the boat. At this distance the explosion made a number of depressions in the hull, and it was clear that at a slightly shorter distance the plating would have been completely ruptured. No damage, however, was done to the inmates, and, consequently, it was demonstrated that the shock of an explosion upon the crew of a submarine boat will be harmless, so long as it is insufficient to rupture the hull of the boat itself. That these experiments do show that the danger to a submarine vessel from the detonation of submerged high explosives is an element to be considered in solving the problems entering into the construction of such a vessel is, however, very apparent. That such a boat, if successful, would be an important factor in naval warfare is self-evident, but after a careful study of results obtained at home and abroad, in connection with the almost insurmountable difficulty of definitely directing such a craft under water, I again referred the question to a board for an exhaustive examination. The report of this board, which was in the main favourable, is now receiving the careful consideration of the department.

Important improvements have been made in the Howell torpedo, which have resulted in making the explosive more efficient. Two of the thirty of these originally ordered have been accepted, and twenty-one are undergoing acceptance trials. The remainder will be ready for testing within a few weeks. The trials thus far conducted having proved satisfactory, the department, in accordance with the provisions of the contract, has increased the number of torpedoes to be supplied from thirty to fifty. All of the Whitehead torpedoes called for in the contract of May, 1891, with the E. W. Bliss Company, have been completed, and carefully conducted trials have, it is believed, shown them to be equal to the very best made abroad. The department entered into a contract with this company for fifty additional torpedoes of an improved type and designated as Mark II. Twenty of these have already been delivered. Nearly all of the launching apparatus connected with these two types of torpedoes have been delivered by the contractors.

Again I feel it my duty to call your attention to the great and pressing need for Congressional action in reference to the *personnel* of the line of the navy. The evils presented in my last report are even greater to-day than then, and will increase until the situation becomes so serious that only the most stringent, far-reaching, and harsh measures will suffice to remove them. The joint commission from the Committees on Naval Affairs of both Houses, referred to in my last report, had the entire subject of the *personnel* under consideration during the greater part of the first session of this Congress, during which plans were presented by myself and officers of the different corps of the navy looking to a thorough reorganisation.

I again renew my recommendation of last year, that the enlisted force be increased by 2000 men. A careful study of the services of the navy for several years past convinces me that the number of vessels which must be kept in commission and ready for service is greater than the present enlisted force allowed the navy will suffice to man. Calculations place this increase at not less than 2000 men, and the law to authorise such increase should be so worded as to permit the department to enlist them whenever needed.

For some years after the subject was first brought to my attention, I was not inclined to believe that the advantages to be derived from a naval war college—as it was established—were sufficient to justify the expenditure necessary to keep it in operation. A visit, however, to that institution at Newport—in the summer of 1893—and a careful study of the whole subject, have sufficed to change my convictions on the subject. My careful examination of this whole question greatly impressed me with the importance of at once establishing the institution upon a firm and substantial basis, and at the same time marking out and limiting within proper bounds its scope and general purposes.

With these ends in view the department detailed Captain H. C. Taylor, United States Navy, as the president of the institution, and afterwards approved a theoretical and practical course of instruction prepared by him. Under the able supervision of this officer, the results obtained during the session beginning June 12th and ending September 29th were very satisfactory, and clearly demonstrated the wisdom of the department's action. Quite a number of officers were detailed to attend the college and participate in its exercises. Able and exhaustive lectures were delivered on sea power, naval tactics, naval ordnance, signalling, fleet manœuvres, torpedoes, tactical and structural questions, electricity, naval hygiene, coast defence, and international law. In addition to these lectures, a feature of the course this year was the study of war problems, specially selected from their natural application to possible future necessities of offence and defence.

Interest in the Naval Militia continues unabated, and it is apparent to the department that its efficiency has materially increased within the past year. During this period organisations have been perfected in Michigan and Connecticut, and the formation of others has been authorised by the Legislatures of Vermont, New Jersey, Virginia, and Georgia. At the present time the number of officers and men of the various States mustered in and serving, is as follows :—Massachusetts, 448; Rhode Island, 113; Connecticut, 65; New York, 442; Pennsylvania, 217; Maryland, 128; North Carolina, 168; South Carolina, 208; California, 320; Illinois, 367; Michigan, 73; total, 2549.

During the first session of the present Congress an Act was passed to promote the efficiency of the Naval Militia which contained provisions authorising the loan by the department of such vessels, boats, and equipments as are not required for the general service, on the requisitions of Governors of States possessing regularly organised naval militia. Under this Act the department has already provided for loaning vessels as follows: The New-Hampshire to New York, the St. Louis to Pennsylvania, the Wyandotte to Maryland, the Nantucket to North Carolina, the Swatara to California.

This movement is still in its infancy, and certainly promises gratifying results, but the exact relations of the Naval Militia to the regular service, and how the two shall best and most efficiently co-operate in any regular plan of national defence, is not as yet distinctly marked out. There are, however, undoubtedly many directions in which the splendid bodies of young men now being organised can in case of need render effective service. We are at present affording them the fullest opportunities for an acquaintance with the service and its requirements, leaving it in great measure to themselves to decide upon what will be the best and most practicable field for their conjunction with the navy. The department will continue to extend all the material aid in its power, and will always be ready, by suggestions and otherwise, to assist in perfecting any plans that may promise to secure the helpful and harmonious co-operation of the militia with the regular navy.

It is noticeable that this movement has developed rare strength and enthusiasm along the great lakes and rivers on our northern frontier. It is also rapidly crystallising and increasing on our western coast, and it is hoped that the authorities of the South Atlantic and Gulf States will encourage the splendid *personnel* which is there ready to be organised. Laws have been passed in many of those States creating a Naval Militia.

The Naval Committee of the House of Representatives has now under consideration the subject of the transfer of the work of the Coast and Geodetic Survey partly to the Hydrographic Office of the Navy Department, and the remainder to the Geological Survey, under the Interior Department. After a careful personal investigation of this subject, begun years ago, I am convinced that the coast survey work proper now remaining to be done along our coasts can be carried on quite as efficiently and much more economically by the Navy Department than under the Coast and Geodetic Survey.

The work of the Coast Survey, for which that organisation is peculiarly fitted, is the topography of the shore lines and immediate adjacent lands. This work has been done with great care and accuracy, but it is practically all completed. Only very small patches of the topographic work along the lines of the Gulf of Mexico and the shores of California remain undone. That this work has long been considered by the Coast Survey officials to be of little immediate value is apparent from the fact that it has been left undone for many years. It is believed that if a very small proportion of the annual expenditures of the survey for the last ten years, say one-tenth, had been devoted to the purpose, this unfinished topography would all have been completed years ago. Should the work of the Coast Survey be transferred to the navy, it is safe to say that all the topographic work along our shores, excluding Alaska, would be completed promptly, as the navy is deeply interested in having complete charts of our coasts.

Without considering the effect of the cessation of this work on industrial conditions, and disclaiming all obligation of the Government to engage in public works for the sole purpose of giving employment to any class, however deserving, I respectfully urge that from the standpoint of national defence it will be unwise to stop entirely the work of naval up-building; that wisdom and experience demand that the present well organised, highly trained, and exceedingly efficient body of mechanics and skilled labourers engaged in the work of naval shipbuilding shall not, at least, be entirely disbanded. With the stoppage of this work many large plants now at work for the navy will have to shut down either completely or in part, and their corps of skilled workmen employed in the various phases of naval construction and development be discharged and scattered, while the plant and machinery for the production of vessels of war must of necessity become idle and be allowed to deteriorate.

I beg to recommend that Congress be asked to authorise the construction of three battleships of about 10,000 tons displacement each, to cost, exclusive of armament, not exceeding 4,000,000 dols. each, and twelve torpedo-boats of from 100 to 300 tons each, at the discretion of the Secretary of the Navy, to cost not exceeding an average of 170,000 dols.

## CLEVELAND INSTITUTION OF ENGINEERS.

### PRESIDENT'S INAUGURAL ADDRESS.

A MEETING of the Cleveland Institution of Engineers was held at Middlesbrough on Monday evening. The president, Mr. J. E. Stead, delivered his address, of which the following is an abstract:—

He said his remarks would bear more upon scientific metallurgical matters, with which he was most familiar, than on purely engineering subjects. He first drew attention to certain facts regarding the waste which had occurred in the past, and was still occurring, in the manufacture of iron and steel, for although all such sources of loss were well known, it was of the utmost importance that they should not be lost sight of, because though at present they apparently could not be avoided, they might in the future prove rich harvest fields for the patient, intelligent, and successful investigator. Refuse of all kinds had been made the subject of careful research, and masses of matter, which at one time was considered as useless, was now utilised to advantage. Formerly the waste refuse—puddlers' slag—was rarely used, excepting in small quantities, and was considered practically of no value. Thousands of tons had been buried, and most of it lost for ever; but thanks to the advances made in the manufacture of basic steel, the phosphorus which was looked upon as the *bête noir*, which rendered useless the otherwise valuable material, was now eagerly sought for, and happy was the man who discovered an old burial-place of such cinder. In many ironworks in the North of England this puddler's slag was being dug out and utilised, and such was the demand for it that all that was now made or found was rapidly disposed of, while as it was getting scarcer and scarcer its price was being augmented. It would appear that the day was not far distant when the supply would fall short of the demand, and some other cheap phosphoretic material would have to be substituted, or a portion of the basic slag from the steel works would have to be charged to the blast furnace in order to obtain the pig iron high in phosphorus, to make basic cinder sufficiently high in phosphoric acid to meet the demand of the farmer, and give a profit to the steel maker. The objection to the latter course was not as great as it seemed, for every substance in the basic slag, with the exception of 10 to 12 per cent. silica and the necessary lime to flux it, was of value in the blast furnace; on an average there was 80 per cent. of valuable matter. The available lime and magnesia were present to the extent of about 30 per cent., and were valuable as a flux, and the oxides of iron, some of the manganese, and all the phosphorus would be reduced and pass into the pig iron.

This basic steel slag was once considered worthless, but in the course of time energetic research proved its undoubted manurial value, and by the simple process of grinding to fine powder it was made into a valuable material. The President mentioned that the suggestion to utilise basic slag in the manner referred to was first publicly made in a paper read before the Cleveland Institution of Engineers, in 1879. [Quite recently Professor Dr. Paul Wagner had shown that the basic slag—which he called Bolckow slag—made from pure Middlesbrough raw iron at the Cleveland Steel Works, was a much more rapid fertiliser than the slags made from specially-produced pig iron, which were exceptionally low in silica. The Professor asserted that the phosphoric acid in Bolckow slag was so easily dissolved, that its efficiency was scarcely less than that of superphosphate. Professor Wagner in his experiments had observed that the most soluble basic slag contained the greatest amount of silica, and those very low in that element were sparingly soluble in a special solution of acid citrate of ammonia, a reagent which was extensively used on the Continent to determine the solubility of basic slags and other phosphates. Professor Wagner concluded that the manurial value of basic slag approximately decreased in value in the same proportion as its solubility in the citrate solution decreased. That practically meant that the rich phosphate basic slags containing 25 per cent. phosphoric acid, of which 50 per cent. or 60 per cent. might be insoluble in the citrate solution, was of no more value than silicious cinder containing 10 per cent. to 12 per cent phosphoric acid. Mr. Stead, thinking that such a statement should not go unchallenged, had repeated and extended Dr. Wagner's experiments. He thought from them that the statements made were stronger than were perhaps justifiable. The subject, however, was of so much importance that he—the president—had embodied his results in a short paper which would be read at the next meeting of the Institution.

With regard to the waste in the manufacture of both acid and basic Bessemer steel, there was more of metal and a corresponding less yield of ingots than theory justified. One source of loss was more or less unavoidable with the apparatus as at present constructed, and that was the mechanical projection of molten metal from the converter during blowing. To alter the apparatus in such a way as to avoid that loss was a study for engineers, and one worth serious consideration. Some loss was also occasioned by the entanglement of small particles of the steel in the scoria or cinder, a condition of things most pronounced in the case of acid Bessemer cinder. From time to time attempts had been made to separate the steel from the Bessemer slag. On one occasion a trial was made at Sheffield, in which Bessemer slags were crushed and the metal separated, and the steel so obtained amounted to 27 per cent. on the raw slag. Slags made on blowing East Coast iron, however, did not contain more than 10 per cent. free steel. Assuming that the average amount present was 7 per cent., and that the quantity of slag produced was 10 per cent. on the weight of the steel produced, that would account for 0·7 per cent. loss in the yield. The cost of grinding and separating 7 per cent. steel from such material by properly constructed grinding and magneto machines would probably be about 2s. 6d. per ton, and the steel separated weighing 1·4 cwt. at scrap price of 42s. might be valued at 2s. 5d. There was thus not much inducement to recover the steel by such a process unless the ground slag could be utilised for some practical purposes. Practically all the entangled steel was recovered from basic slag during its conversion into manure powder.

The President next referred to the waste in the manufacture of ferro-manganese in the blast furnace, a portion of the manganese being found in the slag, 5 to 12 per cent., and a certain quantity was volatilised and passed off as fumes at the top of the furnace. A portion of the waste manganiferous slag was used in the blast furnaces making basic iron. He had hopes that furnaces would be so altered as to meet the required conditions for the more complete reduction of the manganese, and that without increasing the amount of silicon in the metal. Dealing with ordinary blast furnace slag, which continued to rise in higher and higher mounds in the Cleveland district, or was sunk in colossal quantities in the German Ocean, it was remarked that at an early date Mr. Charles Wood and others had converted it into bricks for building purposes. The use of concrete paving flags which contained crushed slag as their base was extending, and they were superior to best Yorkshire flagstones. Some years ago a process by which Cleveland slag could be made into excellent cement was fully described to the Institution, and the pier at Skinningrove was constructed of it. There were other developments under trial now, but it was premature to speak of them.

Turning to the vast loss of heat from the molten slag and iron after leaving the furnace, there was, the President remarked, a seductive field for research. Excepting the application in one single works in the North of hot slag balls for evaporating the salt brine, practically the whole of the heat from the cooling slag from the blast furnaces was wasted. The loss in that direction was so prodigious that it was a disgrace. One of the most important applications to modern practice was the use of the hot metal mixer, originally invented by Colonel Jones, of Pittsburg, and since modified by Herr Massenez. It had resulted in the production of steel of regular quality. During the last twelve months, in Great Britain alone, 338,000 tons had been mixed, and probably a much greater quantity had been mixed outside. About fifteen mixers were now in use, and seven more were in course of erection. Two of these mixers, which held about 150 tons each, had been constructed at Eston, and after a fair trial had given greatly improved results. The result of this mixing was that the length of the operations in the converter, and the amount of scrap used, was made almost uniform, thus increasing the life of the converter linings and bottoms to a considerable extent. It also gave almost uniform carbons in the steel, thereby reducing the percentage of defectives. The mixer had been found even more valuable in the basic than in the acid process, enabling the use of iron lower in silicon.

The Saniter process for desulphurising iron was continued at the Wigan works, and during the past year about 18,000 tons had been treated by it. When hematite forge was treated an average of 64 per cent. of the sulphur was removed; with crude basic iron, 70 per cent., and 40 per cent. of the silicon. The sulphur could be removed with success and regularity at a cost not exceeding 6d. per ton. It was strange that the first Cleveland pig iron treated by the Saniter process in the open-hearth furnace was at the Ligure works in Italy. Cleveland white iron was used. Mr. Stead gave at length particulars of the trials. The steel was of excellent quality, and was probably the first basic open-hearth steel made from Cleveland white iron. Messrs. Dorman, Long, and Co. had recently been successful in making very pure steel from Cleveland white iron in the basic open-hearth furnace, with the assistance of the Saniter invention. Probably when there was sufficient demand for the metal for open-hearth work, blast furnaces might be worked on forge and mottled iron, and the pig iron be purified by Saniter's process, by which means the sulphur and, if necessary, the silicon would be removed in the first instance, and thus less work be left for the open-hearth furnace to do. This was a question worthy of consideration.

Treating of the Howson and Hawdon form of lining blast furnaces, the President said that the advantages claimed were (1) a concentration of the heat at the tuyeres; (2) the melting zone was enlarged—in the horizontal plane—in order to secure and to obtain larger makes and more equal quality; (3) the diameter of the barrel of the furnace was diminished in order to bring the bosh within the melting zone or nearly so, so as to prevent scaffolds, and in order to make it of such size that the materials would pass down to the melting zone in as equal a manner as possible, for with wide bosh and barrel this was not and could not be effected; (4) the top bosh was introduced to support the materials and keep the furnace open for good working, and also to enlarge the capacity of the furnace, which had been much reduced below. The effect of all this had been that one furnace had been reduced from 33,000 cubic feet capacity to 22,300 cubic feet, and was doing better work, was making better quality, and nearly 70 per cent. more iron, working on Cleveland iron. Another furnace working on hematite iron had been reduced to 16ft. diameter and 15,000 cubic feet capacity, and was extremely economical as regarded coke, while very regular as to quality, never having made a pig of forge iron since blowing in eighteen months ago. There could be no doubt that the very large capacity of furnace which was thought necessary was a source of danger to good, steady, and economical working. A small furnace was under much better control, and if it could be deepened so as to give large output and economical results, it must be the furnace of the future. Sir B. Samuelson and Co. had such faith in the Howson and Hawdon furnace, that they had four at work and others would be relined on that system. One great feature was that soft cokes could be used with much more economical results, the upper bosh and smaller capacity diminishing the crushing strain. Distinctly less limestone was used than in furnaces on the old type. The furnaces when on Cleveland iron had produced on the average 802 tons weekly, and when on hematite 1000 tons per furnace.

Mr. W. P. Ingham, of Middlesbrough, had invented a new system for lining blast furnaces, hot blast stoves, kilns, cupolas, &c. Generally in lining circular structures, the bricks were so placed that the vertical joints between them formed lines radiating from the centre. In Mr. Ingham's system, the bricks were made so that the joints were tangential and not radial, and in placing the bricks alternately in alternate layers, each brick tied several others, a combination much stronger than in the older system. Several blast furnaces were now being relined with the new lining.

Mr. Stead next dealt at considerable length with the question of alloying other metals with steel, such as tungsten, manganese, nickel, chromium, and aluminium. This age, he said, must be called the alloy period, for the careful study and application of alloys in the arts and manufactures was becoming more and more pronounced. Steel with 10 per cent. tungsten was extensively used for lathe tools, and was self-hardening. Manganese steel, discovered by Mr. R. A. Hadfield, of Sheffield, afforded the first instance on record in which an element or metal, added to steel in medium quantities, resulted in rotten, worthless material, but when added in larger quantities, between 8 per cent. to 14 per cent. produced steel of an excessively strong and tough character. Castings and forgings, where machining could be dispensed with, have been extensively made of this steel. It was used for grinding and crushing machinery, the wearing parts of dredgers, tram wheels, &c. Dredger pins of this steel after working eighteen months in sand, gravel, and shingle, only wore ¼in., whereas if mild steel pins had been used, four sets would have been worn out. Nickel gave to steel great strength and toughness, but its price was against its use. One of the most important developments in the steel trade was the extensive application of aluminium in its manufacture, and practically half the aluminium made was taken by the steel maker.

The behaviour of arsenic in steel was not like that of either sulphur, or phosphorus, though the theories were that it was. So important was it that this question should be fully investigated that he—the president—and several of his friends had undertaken an extensive study of the matter, and before long their results would be made public. The effect of copper in steel was not thoroughly understood. Some manufacturers would not have any copper in pig, and considered 0·10 per cent. as fatal to the steel produced from it, and yet in America steel with 0·2 per cent. and more had been regularly made of good quality. The physical effect of sulphur in producing red shortness was well established, but its effect on the mechanical properties of steel had not been exhaustively studied. The effect of phosphorus, silicon, and manganese was well understood, but there was much work required to determine the effect of two or more elements when present together in varying proportions.

The President then advocated the amalgamation of the various engineering societies on similar lines to those adopted in the chemical industry, where the Society of Chemical Industry was formed. The Cleveland Institution of Engineers had so far advanced in that direction with the West of Scotland Iron and Steel Institute as to exchange printed "Proceedings" with them, so that every member of each Institution would be supplied with the deliberations and papers of the other.

In concluding the President advocated that in our free libraries and every large metallurgical centre there should be a technical library containing all the standard works which bear upon the particular industry followed. All the transactions of learned, metallurgical, and engineering societies should be found in them, also all the weekly periodicals which contain articles and treat on matters relating to the industry in this country, America, and the Continent. The head of each department should be required to read and review periodically all the current literature bearing upon matters relating to his particular department, and send such reviews, together with his own criticisms, to the head director. Thus he and his subordinates would be kept abreast of the times, and that was very necessary in these go-ahead days.

At the conclusion of the address the President exhibited lantern slides giving diagrams of the Howson and Hawdon type of furnace, and also the Ingham method of lining furnaces.

Mr. Hawdon explained the diagrams of the blast furnace, and said the first was built two years ago, another had been working eighteen months, another which the President referred to as having been at work eighteen months and not made a ton of forge iron had only been blowing some fourteen months. In reply to questions, he said that when producing Cleveland ordinary iron 840 tons per week were made, and when producing hematite 1000 tons. They had six tuyeres to each furnace, and the pressure of blast was 6½ lb. They had tried 6 lb., but found they ran off quality. They used raw limestone, and it was a singular thing that with the heavier pressure of blast they used a smaller quantity than in the old furnaces, both in Cleveland and hematite.

With regard to the Ingham method of lining, Mr. Keith, of the Normanby Ironworks, said they had a new furnace lined in the way shown. It was very suitable for the upper part of the furnace, but below the tuyeres he thought the old way was the better, especially for convenience of repairing.

Mr. Head proposed, and Mr. Hawdon seconded, a vote of thanks to the President for his address, which Mr. Stead acknowledged, and Mr. T. F. Meldrum, of Manchester, then read a paper on "Economy in Steam Raising." A discussion followed.

## LETTERS TO THE EDITOR.

*(Continued from page 545)*

### UENSOLD'S ICE RINK.

SIR,—The statement in your interesting account of the Niagara Hall Ice Rink, that hitherto ice rinks have been constructed on concrete or similar floors, is not quite correct. The Southport ice rink—which was in use for ten years—was built with a wooden floor, on wooden joists, with an air space underneath. The only rink with a cast iron floor was the first one ever frozen—a purely experimental one. The floor was not a cast iron tank, but formed of broad, flat cast iron pipes laid side by side on a concrete foundation. In the second rink frozen flat copper pipes were employed, and similarly shaped pipes were used in the Southport rink, placed on a wooden floor as stated above.

You do not state the thickness of wood used for the floor at Niagara Hall, nor the distance apart of the iron girders. With these data given I think it would be interesting if some one would calculate the weight required to deflect a floor consisting of 5in. of ice—in which a network of 2in. iron pipes is imbedded—when frozen to the wooden floor.

The idea that a natural sheet of ice yields under the movement of a skater is a very common fallacy. If the ice be not frozen to the banks of the pond, and if there be only a dangerous margin of safety, some slight movement may take place, but, as a rule, a natural sheet of ice is perfectly rigid. The difference between a fall on ice and, say, on a roller rink floor, is entirely due to the slide which usually results on ice. A dead fall on ice is as painful to the human frame as a similar fall on, say, wood or marble. A thickness of 5in. of ice is unnecessary and prejudicial in an ice rink. Ice being a non-conductor, it renders more difficult the task of keeping the surface dry when skaters are active and plentiful and the weather is warm. If the floor is properly constructed 2in. of ice are ample, but if a bad system of piping be employed a greater thickness is required to prevent ridges and give a perfectly smooth surface. I have skated on a rink with less than ½in. of ice above the pipes with the surface level as a billiard table.

December 18th. DAVID GUILLOD.

### LOCOMOTIVE CYLINDER CAPACITY.

SIR,—I have read with interest your full and admirably illustrated notice of the new bogie goods engines on the Highland Railway in your last issue. They are undoubtedly very powerful engines, well designed for their work and the character of the line. But in describing them as having "the largest cylinder capacity ever found in a British locomotive" you appear to have overlooked for the moment the first of the two classes of engines constructed by Messrs. Beyer, Peacock and Co. for the Mersey Tunnel Railway in 1885, illustrated on page 150 of THE ENGINEER of February 19th, 1886, which have cylinders 21in. diameter by 26in. stroke. These engines have six-coupled driving wheels 4ft. 7in. diameter, and have therefore a tractive power of 208·5 lb. per pound of effective pressure in the cylinders, as compared with only 165 lb. in the Highland engines.

Further, it will be seen by reference to the leading dimensions given at page 143 of the above last-named issue that in several important dimensions of the boiler and fire-box determining the "power" of a locomotive, the Mersey Tunnel engines of the "Major" class are not inferior to those of the Highland Railway under notice.

NEMO.

December 18th.

### LOCOMOTIVES AND TRAINS.

SIR,—Your correspondent, Mr. McDonald, still seems in doubt about the engines on the express train at Northallerton. Let me, therefore, for his information, once more state that the leading engine was No. 905, an old engine built by Mr. Fletcher over twenty years ago, and that the train engine was No. 1622, one of the latest and heaviest engines in England.

The position of the respective engines in the photograph, taken after the accident, seems to be quite irrelevant.

Friends of the N.E.R., in trying to minimise the fact that the big engine, 1622, had to all intents failed, put forward the excuse that only because there was not sufficient steam to keep the air brake reservoirs fully charged, a pilot was taken at Darlington; but it yet remains to be shown that No. 1622, with—according to "A Practical Man"—only 80 lb. of steam, could pull a train of about 200 tons over such a road at a speed requiring a continuous brake at all.

E. B. D.

London, December 12th.

## AUSTRALIAN ENGINEERING NOTES.

(*From our own Correspondent.*)

A DEPLORABLE railway accident occurred at Sydney station on Wednesday, October 31st, which has resulted in the death of thirteen persons; it is the most serious accident that has ever occurred on the New South Wales lines. An outgoing train at Goulburn ran into an incoming suburban train as the latter was crossing the rails to an out platform. The result of the inquiry showed that the accident was attributable to the driver of the outgoing train starting before the signal was lowered; the interlocking gear was proved to be perfect, and so far as mechanical precautions are possible, everything has been done that is possible to ensure the safety of passengers.

The Reid Ministry—N.S.W.—appear to be doing some practical legislation already which is considered here to augur well for the prosperity of the country. Already a comprehensive Land Bill has passed through committee, and it is intended to bring in immediately a Local Government Bill, to place a land tax on unimproved value of land, and an income tax. As soon as these measures are passed the present protective duties will be taken off. It is expected that the free trade tariff will be brought into operation from July next.

The continued decrease in revenue on the Victorian railways is still an unsolved problem to the people of that colony. The latest phase of the question was the Victorian Premier inviting the Commissioners of the other colonies to meet in conference for the purpose of investigating the matter, but as the Governments of New South Wales and Queensland have declined to let their Railway Commissioners go, the Victorian Government intend to call in some business experts to advise.

A few months ago the Victorian Commissioners lowered their goods rates considerably in certain districts for the purpose of inducing the traffic in wool, &c., to be sent over their lines to Melbourne from the inland districts in New South Wales, also to compete against the road traffic—horse teams—a competition of a minor extent which has sprung up lately owing to want of employment and cheap horse feed. The decrease in revenue for the eighteen weeks of the financial year, compared with a corresponding period of last year, now amounts to £86,566, or an average decrease of £4810 per week.

In the report of the directors of the Sydney Tramway and Omnibus Company, for the year ending September, 1894, they state the continued depression has resulted in a further reduction of revenue amounting to fully £5000, but the loss has to some extent been counterbalanced owing to the very favourable state of the market for forage, together with reductions that it has been necessary to effect. A dividend of 5 per cent. has been declared, while £469 has been carried forward, and £1750 transferred to property reconstruction account. The company is worked on a net paid-up capital of £60,750.

The report of the South Australian railways for the year ending 30th June last is only now just published. The net return on capital expended is shown as 3·54 per cent. The coaching receipts fell off to the extent of £28,525, while the mineral traffic increased £35,197; the latter apparent increase over last year is owing to the strike which prevailed at Broken Hill.

The net decrease on all the items of revenue was £7352, while the working expenses were reduced by £70,530, but while the exigency of the times necessitated a number of the employés being put on short time, with the exception of a few of the professional and clerical staff, no servant of the department has been retrenched or dismissed during the year, except for misconduct.

The following is a comparative summary of the principal items —exclusive of the Palmerston line, Northern Territory:—

| | 1893-4. | | 1892-3. |
|---|---|---|---|
| Average miles open for the year.. | 1,664¾ | .. | 1,662¼ |
| Capital cost on lines open .. .. | £12.154,417 | .. | £11,936,256 |
| Gross earnings .. .. .. .. .. .. | £999,707 | .. | £1,007,059 |
| Working expenses .. .. .. .. .. | £569,592 | .. | £640,122 |
| Net revenue .. .. .. .. .. .. | £430,115 | .. | £366,937 |
| Percentage of working expenses to revenue .. .. .. .. .. .. | 56·98 | .. | 63·56 |
| Percentage of net revenue to capital cost .. .. .. .. .. .. | 3·54 | .. | 3·07 |
| Train miles.. .. .. .. .. .. .. | 3,470,125 | .. | 3,670,390 |
| Earnings per train mile .. .. | 69·14d. | .. | 65·85d. |
| Working expenses per train mile | 39·39d. | .. | 41·86d. |
| Earnings per average mile open.. | £601 | .. | £606 |
| Working expenses per average mile open .. .. .. .. .. .. | £342 | .. | £385 |
| Minerals carried .. .. ..tons | 348,490 | .. | 323,464 |
| Grain carried .. .. .. ..tons | 183,519 | .. | 140,006 |
| Wool carried .. .. .. ..tons | 24,702 | .. | 22,117 |
| Goods carried other than the above .. .. .. .. ..tons | 438,959 | .. | 465,721 |

## AMERICAN ENGINEERING NEWS.

(*From our own Correspondent.*)

*Garbage disposal.*—As already noted in a former letter, the question of the best means of disposing of garbage or house refuse and street refuse is being taken up by several cities, and various systems of cremation furnaces are in use, while in New York the garbage is loaded on dump scows or barges and towed out to sea. This is very unsatisfactory, as the stuff washes up on the shore, spoiling the bathing beaches, especially when in bad weather, or when a bargeman or tugboat captain thinks he can escape notice, the load is dumped before reaching the deep-water limit. The report recently presented by the New York Committee pronounces against the system of towing the refuse out to sea, and concludes that it cannot be dumped within 200 miles of the harbour without defiling the shores. Therefore attention was turned to other methods. In response to public notice, seventy different schemes were submitted, in most cases accompanied with complete drawings of proposed plants, or of those in actual operation. After an examination of these various schemes, twenty-one of them were rejected as impracticable, and the projectors of the remaining forty-nine were invited to appear before the Commission at specified dates to explain in detail the merits and workings of their respective systems. The Commission visited different cities, examined the plants in operation and the systems in use, and made recommendations as follows:—(1) That dumping city refuse in any waters of the harbour, or its adjacent or tributary waters, should be absolutely prohibited. (2) That the ordinance requiring householders to keep separate the garbage, or ashes and other house refuse, should be rigidly enforced. (2) That all house refuse should be collected in galvanised iron vessels with tight-fitting metallic covers, and of such size that when full it can easily be handled by one man. (4) That daily collections of garbage should be made by the city and delivered at the dumping wharves into the temporary storage, or to self-propelling boats of an improved type, furnished by the party having a contract with the city for final disposition of the garbage. (5) That the garbage should be disposed of by a reduction process, producing fertiliser and commercial grease, that the city should invite competition by the various companies controlling such systems, in order that the greatest benefit to the city may result. As the plant for the reduction of the garbage of this city would necessarily be extensive and costly, a contract for a sufficient length of time should be offered by the city to warrant the investment, say, not less than ten years, with proper provision for the transfer of the propety of the contractor, at fair value when the contract is terminated. Ample provision should also be made and abundant security required for the performance of the work on the part of the contractor, in a clean, inoffensive and sanitary manner, and removal of the garbage daily from the city to the reduction works, which should be located at a suitable point beyond the city limits. (6) That a separate collection should be made of the remainder of the refuse of the city not otherwise provided for, which would be used for filling in at Riker's Island or elsewhere, and for the transportation of this material a sufficient number of self-propelled boats of an improved type should be constructed and owned by the city. It should, however, be provided that whenever the whole or any considerable portion of the street sweepings can be disposed of by contract or sale for fertilising purposes, at a price greater than their value to the city for filling, then such disposition should undoubtedly be made of them. (7) That the city should adopt metal water-tight covered carts or trucks of a uniform pattern for the collection of ail refuse, and mechanical dust-collecting sweepers when a satisfactory type can be obtained. That whenever the sweeping of the streets causes dust to arise they shall first be sprinkled. (8) That each refuse cart or truck depositing its contents should be disinfected and washed out thoroughly before leaving the wharf. In conclusion the commission suggests that, if the substance of this report be approved, as little delay as possible should intervene in carrying the recommendations into effect, in order to prevent a recurrence of the serious causes of complaint of the past summer. Six months at least will be required to make the necessary preparations. While the first cost of the necessary plant to carry out these recommendations will be considerable, the commission is convinced that the public good demands it; that the scheme here outlined, fully carried out and properly administered, will abate the nuisances so long complained of and place this city in the front rank of the cities of the world in the cleanliness of its streets and the sanitary and economical disposition of its refuse.

*Tests of capped projectiles.*—A report has recently been made on a series of tests of armour-piercing shells having soft steel caps over the points. In the preliminary experiments the shells tested were of the Wheeler-Sterling 6in. type. The gun used was the 6in. wire-wound rifle, mounted on the centre-pivot gravity return carriage. The distance between the plate and the gun was 330ft. The line of fire was normal at the point of impact. The target was a 6in. curved Harveyised nickel steel plate manufactured by the Carnegie Company, which had been attacked in other tests. The weight of the fragment of plate fired at was about seven tons. The portion struck was in good condition and was held in position by four armour bolts and heavy oak blocking. The plate was unbacked. The charge of powder was 45 lb. The shell had a striking velocity of 1900 foot-seconds, and a striking energy of 2506 foot-tons, or about 358 foot-tons per ton of plate. The cap was fastened to the lower edge of the bourrelet. The shell struck the plate normally 30in. from the bottom, 22in. from the left edge, 30in. from a former impact, and 18in. from a vertical surface crack developed in earlier trials. The shell penetrated the plate, cut through one armour bolt, about 3ft. of oak blocking, 10ft. of earth, 3ft. of solid oak, and buried itself to the depth of 2ft. in the gravel bank behind the structure. When recovered it was found entire and uncracked, only slightly swollen in the rear of the bourrelet, and with the point $\frac{1}{8}$in. to $\frac{1}{4}$in. out of line. The shell was scored from the point to the after portion of the bourrelet, and the extreme point was somewhat blunted. The shot-hole in the plate was 6in. in diameter, and smooth for an impact in a Harveyised plate. The face of the plate was scored irregularly from 2in. to 8in. from the circumference of the shot-hole to a maximum depth of 1in., the back bulge was about 12in. in diameter, and one-half of it was broken off. The disc in the plate was slight, only $\frac{2}{10}$in. The set-back was 1in, and the set to the right 1½in. The plate was not cracked by the impact, nor were the old cracks in it materially affected. The general features of the shell are:—Length with cap on, 19½in.; weight, 104 lb.; weight of cap, 5 lb.; length of cap, 3½in.

## CATALOGUES.

J. P. Hall and Co., Oldham. Illustrated price list of Dynamos.

John Spencer, Wednesbury. Price List of Iron and Steel Tubes.

Mosses and Mitchell, London, E.C. Price List of Vulcanised Fibre.

Beaman and Deas, Warrington. Pamphlet descriptive of Refuse Destructor.

The "Dowson" Gas Engines Syndicate, Limited, London. Illustrated price list.

Henry F. Joel and Co. Illustrated Catalogue of Dynamos, Storage Batteries, Arc Lamps, and other apparatus.

Musgrave Bros., Leeds. Illustrated Catalogue of Hydraulic Machine Tools and other Special Machinery. 1894.

Dorman and Smith, Manchester. Catalogue of Lamp Fittings, Switches, &c. A complete and well illustrated catalogue.

Green and Boulding, London, E.C. Illustrated Catalogue of "Buffalo" Injectors, "Shipman" Engines, &c.

Sir Joseph Whitworth and Co., Limited, Manchester. Illustrated Price List of Screwing Apparatus and Taps, for Hand and Machine Use.

King, Mendham, and Co., Bristol. Illustrated Price List of Electric and Magnetic Experimental Apparatus. This is a very complete catalogue, and should be useful to young experimenters.

Entwisle and Glass, Limited, Bolton. Corrected Wheel List. Sixth Edition. This is a neatly-bound catalogue, clearly printed and arranged, containing tables of wheels of the spur, bevel, mitre, worm, pulley, and fly varieties.

Tannett, Walker, and Co., Leeds. Catalogue of Hydraulic Presses, Cranes, &c. This catalogue is illustrated by means of photographs taken of the cranes, &c., when delivered and at work, which system greatly assists in demonstrating the adaptability of the many various hydraulic appliances made by this well-known firm.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

As next week will prove almost an entire blank for the ironworks, operations this week have been pushed on with all speed. For Australia, New Zealand, and other Colonial markets merchants have recently distributed some fair lines. Competition for these orders is, however, severe, and it is reported that one local firm is prepared to spend £10,000 in the endeavour to obtain a monopoly of the New Zealand galvanised iron market. The price quoted here for corrugated sheets, doubles, is £9 10s. to £9 15s., and in some cases £10 f.o.b. Liverpool. Sheets, ungalvanised, are £6 10s. doubles, and £7 trebles. Much interest is aroused by the information from Sydney that there has been a heavy fall in the price of galvanised iron on that market, due to a new departure by Messrs. J. Lysaght, Limited, of Wolverhampton and Bristol, the proprietors of the "Orb brand," which holds a prominent place in the market. Hitherto this iron has only been purchasable in large parcels, but, in order to meet growing competition, it is now being offered in small lots, at a sliding scale according to quality, and at a lower basis price than has hitherto prevailed. The prices of other descriptions of manufactured iron, as well as pig iron, are unaltered since last report. The steel works are well employed, but complaint is made in this department also of low prices. The Staffordshire Steel and Ingot Iron Company quotes its bridge plates £5 15s., girders and angles £5 5s., bars up to large sizes £5 5s. to £5 15s., tees £5 15s., and boiler plates £6 5s.

"Recent Improvements in Locomotives" was the title of a paper read before the Association of Birmingham Students in connection with the Institution of Civil Engineers, since last report, by Mr. W. Rowland, of Crewe Works. Dealing with the Dreadnought class of engines built by the London and North-Western Railway Company in 1884, Mr. Rowland mentioned as an instance of their capabilities that an engine of that type, in March, 1885, worked the Scotch express from Euston to Carlisle, a distance of 300 miles, at an average speed of 44·7 an hour, between the stations. The total weight of the train was 207 tons, or excluding the engine and tender, 139·10 tons. A load of eighteen coaches weighing about 230 tons could easily be drawn by these engines at 45 miles an hour. In 1891 a still more interesting class of engine was constructed, called the Greater Britain. This ran daily from the 17th to the 22nd of April, 1893, between London and Carlisle, covering 3612 miles. The average weight of the train was 237 tons, and the mean speed 47·66 miles an hour. Upon this engine improvements have recently been introduced. As illustrating the greater demand for increased weight and higher running speed with locomotives during the past twenty years, he pointed out that in 1863 the Scotch express from Euston averaged 312ft. in length, and weighed, excluding the engine and tender, 77½ tons.

Machinery firms in this district are interested in noticing that a new company, under the title of W. and T. Avery, has been registered with a capital of £200,000 in £5 shares, to acquire the business of weighing machine manufacturers, hitherto carried on under the same name at Digbeth, Birmingham. A company under the title of Gibbons Bros. has also been formed, with a capital of £20,000, to acquire the business of Messrs. B. and W. P. Gibbons, gas engineers, and contractors, and brick manufacturers, at Dudley.

As a leading seat of the ammunition trade, Birmingham is much interested in the information that special officers have just been deputed to ascertain under what circumstances the Chinese and Japanese forces are supplied with ammunition, as it is alleged, by English firms. The inquiries that have been made reveal the fact that the United States are as great offenders in this respect as England. Several American officers are in the employ of China, and it is said to have been discovered that these gentlemen have given large orders for ammunition and arms to some well-known American firms. At the same time, it is beyond doubt that much of the ammunition comes from English firms, but, as the orders are executed through another country, there can be no direct evidence against them.

The figure "600" occurring in this letter last week with reference to the employment of traction engines in Herefordshire was a slip of the pen for sixty.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—The year is closing very unsatisfactorily for all branches of trade connected with the engineering, iron, and coal industries of this district. A general slackening off is of course looked for at this season of the year, but there is more than the usual quietude, and an absence of any indication of material improvement when the holiday and stock-taking season is over. The continued further downward tendency in the iron market would seem to indicate rather a want of confidence in the future, and the fact that sellers here and there are still prepared to book forward at under current rates is not at all an encouraging feature, considering that prices have already touched a point that is anything but remunerative to either makers or manufacturers. The outlook as regards the coal trade is perhaps even still worse, and the agreement which was entered into with the Miners' Federation with regard to wages is looked upon as likely to prove a very serious matter for many of the coalowners.

The Manchester Iron Exchange on Tuesday brought together a fairly good attendance, but business remained in just the same depressed condition that has been reported for some time past, and a general absence of buying was again the report all through. Inquiries coming upon the market for pig iron are not only few in number, but, for the most part, extremely small in weight, and prices show a continued want of firmness; makers, rather than allow orders to pass, being disposed to entertain low offers which they were declining a week or so back. For Lancashire pig iron quotations remain nominally unchanged, but as regards forge qualities, for which local makers are asking about 38s. 6d. to 39s., less 2½d. at the works, they are completely out of the market, owing perhaps as much to the absence of requirements on the part of consumers as to the much lower figures at which Lincolnshire iron is being offered.

Occasional small sales of foundry iron are, however, being made by the local makers to regular customers on the basis of about 42s., less 2½, at the works. In Lincolnshire iron some transactions have been put through at excessively low figures, there being no difficulty in buying forge qualities at about 37s., and foundry at about 38s. 6d. net cash delivered Manchester, although makers are in most cases quoting quite 6d. above these figures. Quotations for Derbyshire foundry remain nominally about 43s. up to 44s. 6d. and 45s. net cash for the best brands delivered here, but as there is no buying going on to test prices these quotations are altogether nominal. For outside brands offering here sellers have been prepared to take lower prices, good foundry Middlesbrough being readily obtainable at 43s. 10d. net cash delivered Manchester, whilst as regards Scotch iron, some brands of which have given way about 6d. per ton, Eglinton could now be bought at about 46s. to 46s. 6d. and Glengarnock at 47s. to 47s. 6d. net prompt cash, delivered at the Lancashire pits.

The manufactured iron trade remains in a most unsatisfactory condition—in fact, a representative of one large works told me on 'Change that during his whole thirty years' experience he had never known it to be worse; their works were only being kept going alternate weeks, and such a state of things as the above had never before prevailed, especially at this season of the year. Generally throughout the district forges continue but very indifferently employed, either not starting until Tuesday or Wednesday, or only running a portion of their plant. Prices remain much as last quoted, having, with the present cost of production, got to about as low a point as they can possibly touch. Lancashire bars do not average more than £5 5s., North Staffordshire qualities only in exceptional cases fetching more than £5 7s. 6d., Lancashire sheets ranging from £6 15s., and Staffordshire sheets £7, with Lancashire hoops quoted £5 15s. for random, and £6 for special cut lengths, delivered Manchester or Liverpool. Nut and bolt makers still report only a very limited weight of business coming forward, engineering and other branches of industry not taking anything like their usual weight of this class of material, and prices have to be cut excessively low to get hold of orders.

The steel trade continues all through very quiet, with prices about as last quoted, ordinary foundry hematites averaging nominally 52s., less 2½ per cent.; low-class billets, £3 17s. 6d. to £4; better qualities, £4 5s. up to £4 10s.; ordinary steel bars, £6 to £6 2s. 6d.; and boiler plates, £6 2s. 6d. to £6 5s. per ton, delivered in this district.

In the metal market only a slow hand-to-mouth business is reported, with quoted list rates for manufactured goods unchanged.

The position as regards the engineering industries remains without material change, very few establishments being what may be termed fully engaged, and this chiefly on special work for abroad. For the most part engineers throughout the district are still very indifferently off for orders, and for the present there is no increased weight of work coming forward or in prospect upon which to base any sanguine anticipations of reviving activity next year. Discussing on 'Change the other day the condition of trade with a representative Lancashire engineer who had just returned from a special tour on the Continent, he said that he had been particularly struck with the contrast presented by the position of the engineering establishments in Switzerland and similar works here. Whilst in this country engineering establishments were for the most part dragging on with difficulty from hand to mouth, and many of them extremely slack, in Switzerland they were all busy and full of work. The engineering establishments in Switzerland were, in fact, doing the work which we used to do; and one reason for this was, the better organisation and supervision of the works. The men were more amenable to discipline, and they worked 10 per cent. more time at 15 per cent. less wages, whilst excellent arrangements were carried out for carefully noting every point where improvements could be made and expenditure lessened by trained men, specially set apart for this purpose. In other continental engineering centres also, the large engineering works were decidedly better off for orders than establishments in this country.

With regard to the overtime question and the circulars sent in to the employers in this district by representatives of all the principal engineering trades union societies, asking that restrictions should be placed upon overtime as it is now being worked in some establishments, and abolished altogether on new work, to which I referred last week, I understand that although the leading members of the Employers' Association have had the matter under consideration, no definite action has so far been taken. There is a strong feeling amongst some of the members that if a definite reply has to be sent to the circular, it should be an intimation that if any step is taken in the present depressed condition of trade, it will necessitate a reduction in wages, but whether any course of action such as this will be adopted is only a matter of conjecture.

An ingeniously designed machine specially for cutting spur, worm, and bevel wheels, in brass, by means of a fly-cutter, has just been completed by Messrs. Cunliffe and Croom, of the Broughton Ironworks, Manchester. In this machine the centre of the body is provided with an adjustable mandril holder, admitting mandrils of different diameters and lengths, and so arranged that a number of wheels can be placed in position, divided, and cut in one operation. For cutting spur gear, a perfectly parallel motion is secured by means of a swing frame, which moves in hardened steel centres, connected by levers, and the cutter spindle is always in the correct position for driving and cutting the teeth in any position of adjustment. When cutting worm wheels the entire headstock is thrown to the requisite angle on a radius quadrant, between the headstock and the frame, and for cutting bevel gear the required adjustments are effected by setting the radius quadrant to either side, and throwing the sliding block carrying the end of the cutter spindle over to the right angle by setting a swing frame, which is provided for the purpose. For dividing the teeth a drilled plate is provided, with a spring finger adjustable to all the circles, the periphery of the plate being also machine-cut into a dividing wheel, and fitted with a steel worm and a machine-cut indexed wheel to divide and subdivide into any count of teeth required to be cut. The motion of passing the cutter through the work is controlled by a balance-weighted lever, worked by hand by the attendant. The machine, which has been specially designed for makers of the pre-payment gas-meter attachments to the automatic delivery motion work, and is also particularly applicable for electricians and manufacturers of other intricate appliances, will admit and cut spur wheels, bevel, or worm wheels up to 9in. diameter and 2½in. wide, and produces correct and highly-finished work at a very rapid rate.

All descriptions of fuel continue in the slowest possible demand, either for house fire requirements or steam, forge, and general manufacturing purposes, and with pits in many cases not working three and only in exceptional cases more than four days per week, supplies are more than ample to meet present requirements. All descriptions of round coal are excessively low in price; in fact, 1s. to 1s. 6d. per ton below last summer's rates. At the pit mouth best house fire coals average 10s. 6d. to 11s.; second qualities, 9s. 6d. to 10s.; and common house coals, 7s. to 7s. 6d. up to 8s. per ton; but the minimum figures represent more nearly the average prices at which sales are actually put through. The lower descriptions of round coal continue in but very poor request for steam and forge purposes, and at the pit mouth do not average more than about 6s. 6d. per ton. Supplies of engine fuel are, perhaps, not quite so plentiful as they have been, owing to the present very restricted production of slack, but prices show no improvement, common sorts being readily obtainable at 3s. to 3s. 6d., better qualities 4s. 6d. to 4s. 9d., with some special sorts quoted 5s. to 5s. 3d. per ton at the pit mouth.

In the shipping trade business is very quiet, with extremely low prices taken to effect clearances of common round coals, 7s. 9d. to 8s. per ton representing the figures that have been readily accepted, with better qualities of steam coal not averaging more than 8s. 6d. per ton, delivered at the ports on the Mersey.

*Barrow.*—Business during the past week has been very quiet in the hematite pig iron trade. The new orders booked are of small volume, representing but a limited tonnage, and not anything like what is necessary to keep the present output from running into stock. The stores of iron in North Lancashire still continue to rise, a further 375 tons having been added this week. There are fourteen furnaces blowing, and fourteen standing idle, and in West Cumberland seventeen are blowing, and thirty-one standing idle. Prices are down a trifle on the week, warrant holders now quoting 43s. per ton, net cash. Makers are asking 44s. to 45s. per ton for Bessemer iron. The orders in hand are not large, for on every hand the requirements of consumers are limited.

In the steel trade there is again much quietness. Several of the orders recently booked have been finished and delivered, and the rail mills at Barrow are again standing. Orders for rails are scarce, for the producing power is so great that buyers are kept completely supplied, and new railways are not being put down with much activity. For shipbuilding material there is some inquiry, but it is not a very brisk one. The mills at Barrow are fairly well employed on the manufacture of plates for Barrow, Belfast, and other places; but new orders are coming to hand slowly. The business doing in tin-plate bars is small. Prices this week show no change, and are as follows:—Heavy rails, £3 15s.; light sections, £5 5s.; colliery rails, £5 10s.; ship-plates, £5 2s. 6d.; angles, £5 10s.; boiler-plates, £5 12s. 6d.; and tin bars, £3 17s. 6d.

In the engineering and shipbuilding trades there is nothing new to report. The shops are well employed, particularly in the engineering department; and on the shipyard side there is considerable activity noticeable, and all orders are well in hand. New orders are scarce.

Iron ore is in poor demand at 8s. 6d. to 9s. 6d. per ton net at mines for average sorts. Coal and coke are in fair consumption.

The shipping trades are depressed, both on coasting and foreign accounts. The exports of iron and steel show a decline on the year of 2000 tons.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

THE mild weather which at present prevails in this district has the effect of checking the demand for household sorts, and interferes as well with the consumption of coal for all heating purposes. Many of the collieries are now making on an average from three to four days a week, the only instance where five days are worked being at pits which are busily engaged on contract account. The stacking of house coal has commenced at not a few of the thick seam pits, which is a very unusual thing at this season of the year. London has taken a very moderate demand by rail of both Silkstone and Barnsley this week. Agents in the metropolis state that business is very quiet, and sales can only be effected at low rates. This is on account of seaborne fuel being sent in large quantities, and owing to the cheaper rates paid for this mode of carrying, stocks are more easily disposed of. Summer prices are hardly kept up. Last week's quotations are still ruling. Silkstone is at 9s. to 10s. 6d.; Barnsley House, from 8s. 6d. to 9s. 6d.; Flockton, about the same rates; secondary qualities at 7s. to 7s. 6d. per ton. The steam coal trade is fairly active for this period of the year. A good tonnage is being dispatched on the Hull and Barnsley Railway from Denaby, Stairfoot, and Cudworth. The business with Hull and the other Humber ports is well up to the average; the export trade, in spite of the railway rate to the seaboard, shows a disposition to steadily advance. Inquiries for next year's export trade are reported to be pretty numerous, and there is every probability of a larger business being done in Barnsley hards. In railway contracts the Great Eastern Railway has been taking some supplies of house and gas coal from Doncaster. Tenders were submitted a fortnight ago, but as yet not much business has been done. The companies whose contracts are already placed are taking a good average tonnage. Prices range from 7s. 6d. to 8s. per ton for South Yorkshire hards, secondary qualities only fetching 6s. 9d. to 7s. 3d. per ton. Gas coal is in large demand, mainly on contract account, prices being from 7s. 3d. to 8s. Small coal and slack are in a very depressed condition, supplies being largely in excess of demand, and prices very low. Common pit slack can be had at 3s. per ton, and riddled qualities at from 4s. to 5s. Smudge is as low as 1s. 9d. to 2s. per ton at the pits. The request for coke is well sustained, and a good tonnage continues to be forwarded to North Lincolnshire and Derbyshire, prices ranging from 9s. to 11s. per ton.

The iron trade keeps as dull as ever, and the low prices already quoted are not likely to be altered this year. Hematites delivered in Sheffield remain at 50s. to 52s., according to brand; and Lincolnshire forge iron is at 38s. per ton. Bessemer billets are £5 7s. 6d. per ton when largely ordered, and a little firmer for smaller quantities. For Siemens-Martin steel the brisk demand noted during the year has been maintained. Swedish Bessemer billets exhibit more animation, and in both branches brisker trade is anticipated in the early part of 1895. The rolling mills are rather better engaged on orders for the city, which practically means that the lesser staple industries are affording a larger amount of work to the employés. Still, a good many workmen are applying for engagement at the offices of the larger and more enterprising firms, where the condition of affairs is reported to be much better than was expected two months ago. A very important business indeed has been done by several of our East-end steel houses, in the better classes of steel required for military, watch, clock, and similar purposes.

Railway companies are giving out very few orders owing to the unsatisfactory traffic returns. A few fair orders for rolling stock have recently been placed. The productive powers of our Sheffield establishments, however, are now so large that an immense volume of work is required to keep them fully employed, and as there is now no probability of any such stimulus being obtained this season, there will be not a little distress amongst workpeople, who have been so indifferently employed during the whole year. In fact, with the exception of the armour-plate department, very few of the heavy trades have given regular work to their hands this season. A great disappointment has been the absence of orders for ordnance and shells. A large amount of money has been spent in laying down costly plant for the production of armour-piercing projectiles, and a staff of skilled artisans has been kept in the expectation of adequate work being found for them—the necessary complement, as it was thought, of the Admiralty programme. But these anticipations have not been realised, and the firms who have laid themselves out for this special work have found the department entirely unremunerative through sheer lack of employment. The armour-plate firms are working at high pressure to expedite the delivery of plates ordered this year under the new Admiralty programme. These are for H.M.S. Magnificent, Mars, Majestic, Jupiter, Prince George, Hannibal, and Victorious. Each ship requires 2500 tons of armour-plates. The Magnificent, which was launched on the 19th inst., has just been a year and a day in completion. The superficial area of the citadel armour of the Magnificent is about 8150ft., and the thickness 9in., 12in., and 14in., and the weight 1460 tons. Work is also in hand for the cruisers Powerful, Terrible, Dido, and Isis.

In the lighter trades a steady improvement is noted in the demand for cutlery from America, and a fairly satisfactory volume of business is now being done. When the commercial aspect in the States has had time to clear, the full benefit of the reduced tariff will be felt. The outlook at present is unusually gratifying, as the goods sent to the States increase every week. There is also a perceptible change for the better from Australia, which is steadily recovering from a succession of severe financial distresses. There is more doing as well with South American markets, particularly as regards the grades of cutlery peculiar to these countries, as well as in tools and the higher class of forks and spoons. Silver and electro-plate are in brisk demand, the output of sterling silver work increasing every week, while the call for the best plate is not seriously affected by the preference shown for silver goods.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

IT is decidedly the exception to find anyone engaged in any branch of trade of this district expressing satisfaction with either his position or prospects, but the most general complaint is that it is almost impossible to make receipts cover expenditure, and as far as regards the capitalist a large amount of work has to be done for nothing. The year is closing with business in a very unsatisfactory state; indeed, taken as a whole, it has not at any one time been worse during the year, and prices generally are at the lowest point which has been reported during the twelve months. The highest prices ruled in the first month of the year, when No. 3 Cleveland pig iron was 1s. 6d. above the present figure; grey forge pig, 2s.; hematite pig iron, 3s. 6d.; steel plates, 12s. 6d.; steel angles, 7s. 6d.; common iron bars, 5s.; iron ship-plates, 5s.; and iron angles, 7s. 6d., and it is much more difficult to secure orders. To those pig iron makers who have to buy their materials in the open market the task of keeping their furnaces going without loss must be almost impossible, seeing that 12s. 3d. per ton delivered on Tees-side is the rate to be paid for coke, 4s. for limestone, and something like 5s. 6d., the average price of Cleveland ironstone. One of the leading ironmasters has publicly stated that several of the Cleveland pig iron making establishments are being carried on at a loss, and if we look at the prices of materials and the sum paid for the pig iron itself, such a statement may well be believed, more especially where the furnaces are producing hematite pig. The ore at 12s. per ton will cost per ton of pig iron made something like 24s., the limestone 1s. 6d., the coke at 12s. 3d. per ton 13s., and labour 3s., or altogether 41s. 6d., which is only a little under the present selling price of mixed numbers of Cleveland hematite, and in this calculation there is nothing allowed for water, depreciation, interest on capital, rates and taxes, &c. There is no question that the prices of materials have not this year come down in the same proportion as the prices of the manufactured article, but that, as far as regards pig iron, is due to the fact that the consumption has not only not been reduced, but has increased, and the producers of the raw materials have had no difficulty in disposing of all they had to sell. Under such circumstances it was not likely that they would reduce their prices. That the consumption has increased is indicated by the fact that while a year ago only 84 furnaces were in operation, now there are 95, and this latter number have been working for some months. Thus the production of pig iron has been augmented, and, in fact, will be the largest that has ever been recorded in the North of England, the estimate for the year as compared with the actual figures for last year, and with 1890, which was the previous best year, being as under:—

| | Cleveland<br>Tons. | Hematite<br>Tons. | Total<br>Tons. |
|---|---|---|---|
| 1894 .. .. .. | 1,423,000 .. .. | 1,540,000 .. .. | 2,963,000 |
| 1893 .. .. .. | 1,388,043 .. .. | 1,336,141 .. .. | 2,724,184 |
| 1890 .. .. .. | 1,539,250 .. .. | 1,306,839 .. .. | 2,846,089 |

Thus the production exceeds the previous best by over 120,000 tons, and over half the iron made was other than ordinary Cleveland. The best year for Cleveland ordinary iron alone was in 1881, when 1,998,824 tons were made. Never was there such a large import of foreign ore, the quantity received in the Tees alone will reach 1,468,000 tons this year, as compared with 1,268,702 tons in 1893, and 886,352 tons in 1892. And from the Cleveland ironstone mines alone over 5,000,000 tons will have been raised, or about 375,000 tons more than in 1893. But in spite of this increase in make, it is to be feared that the balance of the makers at the bankers will not have increased much, for prices have not on the whole been unsatisfactory, and the production has been kept somewhat in excess of the requirements during the greater part of the year, so that stocks of Cleveland iron will have increased in the aggregate over 43,000 tons, and probably a good deal more than that in hematite, but there are no complete figures available, though in Connal's warrant stores alone the stock of hematite iron will have increased 45,000 tons, or more than in Cleveland iron altogether.

Makers have not this week reduced their prices of Cleveland pig iron below 35s. 3d., but merchants and speculative holders have been selling at 35s. 1½d. for prompt f.o.b. delivery, as some of them do not want to carry iron over to next year, and various speculators are not in a position to accept the iron due to them for delivery this month, and have to sell at what they can get. It is thought that we shall see 35s. generally taken before the year is out, and this is the minimum of the year. No one is buying for forward delivery when prices are drooping, and the production exceeds the requirements. Cleveland warrants have declined to under 35s., for on Wednesday 34s. 11d. cash was taken. The stock of Cleveland pig iron in Connal's warrant stores on Wednesday night was 92,047 tons, or 834 tons increase this month, and 9408 tons decrease for the year. The lower qualities of Cleveland pig iron have not fallen in sympathy with No. 3 and warrants, as they had their season of declining prices some time ago, and they are not now being offered so freely as they were. Thus No. 4 Cleveland pig iron is quoted at 34s. 6d., and grey forge at 33s. 6d., and makers are pretty firm at these rates. Mixed numbers of hematite pig iron are readily obtained at 42s. 6d. per ton, producers being anxious to sell as their stocks are increasing. They will obtain a little amelioration in the cost of foreign ore, because freights are somewhat easier, and almost anyone will sell good Rubio at 12s. per ton, delivered on Tees-side next year; while some cargoes for immediate delivery have been sold at 11s. 10½d. The closing of the Black Sea ports has thrown a considerable amount of tonnage into other trades, and ore shippers have this week had no difficulty in engaging vessels at the lower freights, which are 4s. 9d. Bilbao-Middlesbrough, 4s. 6d. Bilbao-Jarrow, 7s. 7½d. Huelva-Middlesbrough, 7s. 10½d. Benisaf-Middlesbrough, 7s. 10½d. Garucha-Tyne. The best price for Rubio ore this year has been 12s. 9d., paid in March, so that the fall has been fully 9d. per ton. The ironmasters in Cleveland have arranged to give 2s. 6d. in excess of his regular wages to every shift man at their blast furnaces who does not absent himself from work, except by arrangement with the foreman, between December 24th and January 2nd. The men wanted this bonus given for Christmas day and Christmas night alone, and not to extend over the seven shifts.

The finished iron and steel manufacturers report no change this week, but they are rather better off than they were last month, and adhere to their higher quotations. For steel ship plates, £4 15s., less 2½ per cent. f.o.t., is quoted; steel boiler plates, £5 15s., less 2½ per cent. f.o.t., and iron plates are at the same figures. Iron and steel ship angles are both at £4 10s., less 2½ per cent. f.o.t., and engineering angles, £4 15s., less 2½ per cent.

It is satisfactory to see that more desire is shown to give out orders for new vessels, and this must have a good effect upon the plate and angle trades. One of the Tyneside yards has got an order within the last few days for one of the largest vessels ever built in this district. Her deadweight capacity is to be 10,200 tons, and beam 56ft. Messrs. Wm. Gray and Co., of West Hartlepool, have also secured orders for two large vessels. They have during this year launched seventeen vessels—all steel screw steamers—of 49,733 tons and 20,990 horse-power, while Messrs. Furness, Withy and Co. have launched nine vessels—all steel screw steamers, except one of iron—of 23,319 tons and 2025 horse-power. Messrs. R. Irvine and Co. have launched three steel screw steamers of 6141 tons and 2765 horse-power. Altogether at the Hartlepools twenty-nine vessels have been launched, or five more than last year, and the total tonnage is over 79,000 tons, or 13,000 more than in 1893.

The engineering trade is quiet, as it has been all the year. During this year the Central Marine Engine Works, at West Hartlepool, have provided engines for nineteen new vessels, besides which two vessels have had their boilers renewed, and their engines converted to high-pressure compounds. Four boilers have been built for dredgers and tugs, making altogether forty-four boilers of the marine type built at the works. The total production falls considerably short of that of last year, which may be partly attributed to the prolonged strike of moulders and patternmakers. The average indicated horse-power of the new engines built this year has been 1571, as against 1548 in 1893, and 1500 in 1892. The total number of vessels dealt with was twenty-one, and the indicated horse-power of the engines was 32,050, while in 1893 the number of vessels was twenty-five, with 36,550 indicated horse-power.

The death is announced at Grange-over-Sands of Mr. Edgar Gilkes, who was one of the pioneers of the Cleveland iron trade. Mr. Gilkes was a native of Berkshire, and came into the North in 1839, where he was engaged at Shildon as one of the engineers of the Stockton and Darlington Railway. In 1843 a branch establishment was started at Middlesbrough under the name of the Tees Engine Works, for the repair of rolling stock, and Mr. Gilkes was made manager. Shortly afterwards he joined Mr. Isaac Wilson, the late member of Parliament for Middlesbrough, in carrying on the works under the style of Gilkes, Wilson and Co., that being the first engineering establishment at Middlesbrough. They built a considerable number of locomotives for the old Stockton and Darlington. At the works they also made a speciality of the construction of viaducts. In 1852 Mr. Gilkes joined in erecting blast furnaces, and his firm were one of the first to follow the example of Mr. John Vaughan, soon after the discovery of the main seam of Cleveland ironstone. He was one of the first councillors of the borough of Middlesbrough, and filled the post of Mayor in 1863.

The coal trade is dull, shipments falling off and prices weak. The North-Eastern Railway Company have placed their contracts for next half-year's supplies of locomotive coal at 8s. per ton for the Northern division, which is equal to about 9s. 6d. f.o.b. or 1s. below the contracts now in force. The supplies will be obtained from the Stella, Lord Durham's, the Stanley, and Sir James Joney's collieries. The price of best steam coal is 9s., and small 4s. f.o.b. The gas coal syndicate keeps the price of best at 7s. 3d., and the cokemakers' syndicate does not allow the price of best coke to fall below 12s. 3d. per ton, delivered on Teesside. The Durham Miners' Council have intimated to the owners' secretary that they do not this year intend to stop the pits to take the usual week's holiday between Christmas Day and New Year's Day.

The members of the Boilermakers' and Iron Shipbuilders' Society—one of the most important trade organisations in the country—have adopted, by a substantial majority, their secretary's suggestion that the society shall withdraw from the Trades' Union Congress, owing to the power that the new unionism has obtained there, and the impracticable character of the resolutions which are now discussed and passed there. Probably more of the older unions will follow the example of the Boilermakers' Union.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

The Glasgow pig iron market has been depressed. Large quantities of Scotch warrants were disposed of last week, prices falling about 6d. per ton. This week the downward tendency has continued, and business has been down to 41s. 10d. cash. Cleveland warrants have sold in small quantity at 35s., showing a decline of 6d. on the week, and Cumberland hematite at 43s., a fall of a similar rate. These declines have caused a good deal of uneasiness in the market, especially as some influential holders, who supported prices for a long time, are understood to have cleared out and gone on the bare tack.

An additional furnace has been lighted, and there are now forty-six producing ordinary, and twenty-five hematite pig iron.

There is a quiet business in makers' iron, the prices of which have been receding in sympathy with warrants. G.M.B., f.o.b. at Glasgow, No. 1, is quoted 43s. 9d. per ton; No. 3, 41s. 9d.; Monkland, No. 1, 45s.; No. 3, 42s.; Carnbroe, No. 1, 46s.; No. 3, 44s.; Clyde, No. 1, 49s. 6d.; No. 3, 46s. 6d.; Calder and Gartsherrie, Nos. 1, 51s. 6d.; Nos. 3, 47s. 6d.; Summerlee, No. 1, 52s. 6d.; No. 3, 47s. 6d.; Coltness, No. 1, 54s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 47s.; Eglinton, No. 1, 47s. 6d.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 47s. 6d.; No. 3, 45s. 6d.; Shotts at Leith, No. 1, 53s.; No. 3, 50s. 6d.

The shipments of pig iron from Scottish ports in the last week amounted to 4875 tons, compared with 5616 in the corresponding week of last year. There was shipped to Italy 390 tons, Australia 350, India 234, South America 60, France 61, Germany 175, Holland 220, Belgium 30, China and Japan 400, other countries 60; the coastwise shipments being 2866, against 4599 tons in the same week of 1893.

There has been rather more doing in the malleable iron trade for home consumption, but the shipping inquiry is reported to be in a backward state. The steel makers have reduced prices 2s. 6d. per ton, finding this to be a necessity on account of one or two firms taking work at lower rates. The output is large and competition keen. The demand for shipbuilding steel has lately been on the increase in consequence of the placing of numerous contracts for the shipbuilders.

The locomotive builders are now getting well supplied with orders, and boiler makers are in many cases doing well, but the general machinery trades remain quiet.

The iron and steel manufactured goods shipped from Glasgow in the past week embraced locomotives valued at £2070, sewing machines £5280, other machinery £10,400, steel goods £8193, and miscellaneous iron goods £16,696.

The coal trade is flat, especially in the shipping department, the shipments, compared with those of the preceding week, showing a decrease of fully 30,000 tons. About 10,000 tons of the decrease arose at Glasgow, and the remainder at Ayrshire and Fife ports. Business in Ayrshire is in a very backward state, the export trade particularly having fallen off materially.

Full returns are now available regarding the Clyde shipbuilding trade in 1894. The launches number 75 sailing vessels, with a tonnage of 72,130, and 182 steamers of 268,755 tons—total, 340,885 tons, compared with 280,160 in 1893. The output has only been exceeded on two previous occasions, viz., in 1882, when it was 391,934, and in 1883, when the highest tonnage ever launched—419,664—was launched. The year has been a busy one in the engine shops, which turned out 290,945 indicated horse-power, against 256,545 in the preceding year. It is calculated that the work on hand in the Clyde shipyards amounts to 225,000 tons.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

Last week proved, as anticipated, a busy week in coal shipping at all ports, Cardiff alone dispatching over 300,000 tons. During the week I had an opportunity on both the chief lines of rails from the principal collieries, those of the Taff Vale and the Rhymney, of seeing the coal traffic, and it was considerable. The collection of first-class steam coal at Llanishen, Roath sidings, and Cardiff terminus was excellent.

Some more big orders have been booked for coal, in addition to those I have announced of late. On 'Change this week at Cardiff it was reported that the Campagnie Generale Transatlantique had concluded contracts with the Harris Navigation—now Ocean—for 50,000 tons steam coal, and with the Ferndale Company for 60,000 tons, to be delivered in 1895. The exact figures for which both were booked are not known, but the impression is that they range between 10s. 9d. and 11s. per ton. In either case the outlook is satisfactory, and shows that the opinion in good quarters of fair prices being retained is a sound one.

Prices have been fairly well maintained of late. Quotations on 'Change, Cardiff, mid-week, were as follows:—Best steam, 11s. to 11s. 3d.; seconds, 10s. 3d. to 10s. 6d.; dry coal, 9s. 9d. to 10s.; small, 5s. to 5s. 6d. This may be regarded as a good price for small, which is rather a glut in the market. I saw a large quantity tipped at a leading colliery a few days ago, which, unless prices advanced materially, would scarcely pay to be re-trucked.

In house coal there is a good demand, but coal owners express some little disappointment that demands have not increased in sufficient volume to send prices up. Practically quotations remain. The latest at Cardiff are:—Best household, 10s. 6d. to 11s.; No. 3, Rhondda, 10s. 3d.; brush, 8s. 3d. to 8s. 6d; small, 6s. 9d. No. 2, Rhondda, 8s. 6d. to 8s. 9d.; through, 6s. 6d.; small, 4s. 6d. Quotations in coke remain unaffected, and very likely will continue so until there is an improvement in the iron and steel trades. Cardiff prices are:—Furnace, 14s. to 14s. 6d.; foundry, 15s. to 15s. 6d.; special foundry, 21s.

Patent fuel is only in moderate request; prices remain. The pitwood stocks are now filling up, and prices are getting easier. Cardiff quotations now are 15s. 6d. to 15s. 9d. for ordinary ex ship.

A local authority has published, at an opportune moment, a list of the losses to capitalists which have occurred in the coalfield of Wales—a formidable sum, by the way—showing the necessity that the men, ere abandoning the sliding scale and bringing about confusion in the trade, should exercise the greatest caution. The contention on the side of capitalists is that their bed is not one of roses, and that losses such as £200,000 in a single venture, closed pits in one direction, and long periods of inaction in another, might fairly tempt men of means to choose a less hazardous employment for their money than coal-mining affords.

That the men are beginning to see that they have been too impulsive, in giving notice to terminate the sliding scale, is evident from recent occurrences. On Tuesday there was a meeting of colliers' representatives at Cardiff, Mr. Abraham, M.P.—Mabon—in the chair. The meeting was called to consider the financial position of the sliding scale and other business. It transpired during the meeting that efforts have been made of late to bring about an interview with the employers' representatives, with a view to discuss a revised sliding scale, but that, so far, they had been unsuccessful—a fact the meeting regretted. An annual levy of 6d. per member, in support of the sliding scale committee, was called for.

Some of Sir W. T. Lewis's latest efforts in ameliorating the condition of the working classes have been in the establishment of hospitals in the colliery districts. Merthyr and Aberdare now have one each, thanks to him, and both have done great service this week. I learn from the secretary of the Merthyr Hospital that Sir William called there a day or two ago, and, finding that colliery accidents and general accidents were treated in the same ward, submitted that, if a receiving ward were built by the committee, he would give £1000 to endow one bed for colliery accidents. This, of course, was gratefully received, and has given rise to much satisfaction.

I am still unable to report any change for the better in the iron and steel trades, which have drifted into such a stagnant condition that even on 'Change quotations are ignored, and all kinds and descriptions regarded as "unchanged." Things are not only in a slow state, but it is quite possible there may be only partial stoppages. As for steel rails, it was pleasant to see two cargoes of 160 tons a day or two since going to a local railway from Newport, Mon.

In the bar there is only a quiet average trade, and until the wage difficulty in the tin-plate trade is settled at Swansea and Llanelly, little more can be anticipated. Last week I saw some good make from the Treforest Works, and here and there workmen are going on fairly in harmony with employers; but the general condition is unsatisfactory. Last week, owing to the non-arrival of tonnage at Swansea, only 42,999 boxes were dispatched of tin-plate, while 75,153 boxes were received from works. Stocks are now at 282,459 boxes. However, though the outlook is bad there are some encouraging signs. Nine steamers are due in to load at Swansea, and any day I may have the gratification of announcing, not only a brightening up of prospects in the tin-plate trade, but the conclusion of satisfactory arrangements between the men and employers. Some employers have succeeded in effecting a reduction of wages for a few months, but there is no official statement made, and arrangements fluctuate considerably, some being at the rate of 7½, I hear, and others 25 per cent. off existing wages. At Lydney a 10 per cent. reduction has been effected, and it is expected a similar one will be carried out at Melingriffith, near Cardiff.

On Saturday last there was a special meeting held in Cardiff of the council representing the workmen in the tin-plate trade of South Wales and Monmouthshire; 80 delegates were present. The chief subject was the reduction in wages demanded by employers, and it was resolved to solicit a vote on the subject from the several branches.

On the same day it was under discussion at Swansea, at a large meeting, to form a rival union. The question was adjourned for a fortnight.

A temporary stop has taken place at Blaina Iron and Tin-plate Works on account of slack trade.

The Saxony, a fine liner, belonging to D. McIver and Sons, of Liverpool, came into the Roath Basin this week to load, and attracted a good deal of attention. She is under charter to the River Plate, with Messrs. Worms, Josse and Co.

Newport, like Cardiff, is adding to its steamers. The Refugio, a new steel screw steamer, of the Remedic Steamship Company—Orders and Handford, Newport—has just completed a most satisfactory trial trip, and is loading coal at Cardiff for St. Nazaire. She was built by the Campbelltown Shipbuilding Company, and is a fine construction, with all modern and latest appliances. Her engines are on the triple-expansion principle, and are by Kincaid and Co., of Greenock.

The electric lighting of Swansea, as regards the compulsory area, has been decided upon, on the high-tension alternating current, and a refuse destructor is to be used in connection.

A register of unemployed men is to be kept by the Cardiff Corporation, the influx of strangers to the port being so great, and it is found that vessels are becoming larger, yet fewer in number, and less hands are required. Work for 100 men for three months has been laid out.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

The reports concerning iron trade over here continue unfavourable, and the general tone of the market is anything but firm, the more so because appearances seem to indicate that an improvement will not take place for weeks, probably months.

No material change can be stated to have occurred on the Silesian iron market since former letters. There is, perhaps, a slightly better demand for some articles, and activity is tolerably well maintained, especially at the rolling mills, but with regard to prices no improvement is perceptible, and makers are content if they can realise the cost of production. Export is worse than it has been for several years.

On the Austro-Hungarian iron market very few contracts have been booked upon the week, the reserve among consumers and dealers having increased rather than diminished. All sorts of iron, raw as well as finished, are being offered at the lowest prices imaginable. There is still much iron coming to the Austrian market from Germany, and in a great many cases the inland producers were beaten by their rivals. Just lately, however, the Austrians have, on the other hand, been successful in getting a German contract; underquoting several of the Rhenish-Westphalian firms, the Wittkowitz Ironworks got an order for steel tires at M. 290 p.t. free Oderberg.

In France the state of the iron industry leaves much to be desired, and there are many establishments which can only be kept going part of the week. In Paris prices are nominally unaltered, but in reality any price almost is accepted. In the Meurthe-et-Moselle department the tone among ironmasters is disheartened; it is expected that the meetings of the different syndicates which take place at this time of the year will put a stop to the quarrels and the underquoting of the ironworks.

The condition of the French coal market is not a good one. A number of collieries are only being worked five days in the week; stocks are heavy, and the coal market is altogether suffering from over-production, but still the coal companies cannot resolve on a decided restriction of output, which would be the only means to overcome the difficulties with which producers have had to battle for more than two years. Noteworthy changes in quotations have not taken place recently. Output of pit coal in the Nord Department has been during the last ten years as follows:—

| | Tons. | | Tons. |
|---|---|---|---|
| 1884 .. .. .. .. | 3,401,517 | .. 1889 .. .. .. | 4,719,328 |
| 1885 .. .. .. .. | 3,582,760 | .. 1890 .. .. .. | 5,184,774 |
| 1886 .. .. .. .. | 3,910,141 | .. 1891 .. .. .. | 4,759,162 |
| 1887 .. .. .. .. | 4,197,795 | .. 1892 .. .. .. | 4,637,316 |
| 1888 .. .. .. .. | 4,416,185 | .. 1893 .. .. .. | 4,707,368 |

The number of men employed in 1893 was 20,890, against 20,809 in 1892. Of these 16,060 men were working underground, and 4830 aboveground.

There is no change in demand or employment on the Belgian iron market. Prices are tolerably firm, producers having, at a recent meeting, resolved to steadily maintain list rates for at least some weeks. Comparing the figures for November 1st and October 1st of present year, little or no difference can be perceived. Luxemburg foundry pig has been well maintained at 48f. p.t.; basic, 51f. p.t.; Luxemburg forge pig rose from 43f. on 44f. p.t. Bars, No. 1, still note 115f. p.t., free Belgian railways, while 110f. p.t. is quoted f.o.b. Antwerp. Plates, No. 4, have decreased from 220·50f. p.t. on 217·50f. p.t. free Belgian railways. Steel rails remain unaltered at 95f. p.t.

In spite of considerable quantities being imported, pig iron continues to be tolerably well inquired for. Since the beginning of the year, import of pig iron into Belgium has increased 71,000 t., or 70 per cent., during the first nine months of the year. 170,482,460 t. were imported, against 99,471,928 t. in the previous year, and against 108,815,094 t. in 1892. For September alone figures are 36,998,394 t. in 1894, 30,165,556 t. in 1893, and 30,375,220 t. in 1892. On the 1st of November 28 blast furnaces were in blow out of 42 existing, of which 14 produce forge pig, 3 foundry pig, and 11 basic. The following shows production of pig iron in October, and for the first ten months of present year and of the year before.

| | October. | | January to October. | |
|---|---|---|---|---|
| | 1894. | 1893. | 1894. | 1893. |
| | t. | t. | t. | t. |
| Forge pig .. | 37,820 | .. 33,480 .. .. | 338,060 | .. 325,080 |
| Foundry pig.. | 6,820 | .. 6,510 .. .. | 66,220 | .. 63,210 |
| Basic .. .. | 20,860 | .. 20,150 .. .. | 343,660 | .. 195,650 |
| | 65,500 | 60,140 | 747,940 | 583,940 |

A quiet tone prevails on the Belgian coal market. Prices for house coal are, on the whole, well maintained, although demand has been but small hitherto. Engine classes of fuel and coke are also pretty firm in quotation. Export in artificial coal was for September of present year, 49,921 t., against 56,324 t. in the year before, and against 33,804 in September, 1892. Total export during the first nine months of present year amounted to 441,881 t., against 370,906 t. for the same period the year before, and against 253,040 t. in 1892, which shows an increase of 188,841 t., against 1892.

Rhenish-Westphalian iron industry continues in a lifeless condition, and there have been more blast furnaces blown out during the week. Almost no orders for pig iron are received from abroad, and the works of the Rhenish-Westphalian district have only secured contracts for one or two markets at the best. The producers of the Siegerland have been more fortunate; some of them report their order books pretty well filled. The rolling mills are in a miserable condition, the demand for bars and girders becoming more flat from week to week. Hoops are also neglected, and the same can be told of plates and sheets.

Everything seems to be going from bad to worse, the slightly improving demand which was a short time ago noticeable for some articles of manufactured iron having now given place to an extreme depression and general lack of employment. Foundries, as well as machine and wagon factories, remain in irregular activity, and justly complain of the low prices they realise for their work. At a recent tendering at Cologne, lowest offers were, for steel rails, M. 113·70 p.t.; sleepers, M. 108·70 p.t.; and for fish-plates, M. 113·70 p.t., free at works.

The collieries of the Saar district produced in November of present year 550,200 t., consumption amounting to 560,765 t. Output for the same month last year was 524,400 t.; consumption, 543,400 t.

A Large Sewer Tunnel being built at Niagara, Falls, NY.,. will be 7ft. by 9ft. in cross section, and about 3500ft. in length. In connection with this tunnel over a mile of 5ft. brick trunk sewer is to be built, the aim being to provide for the needs of a large manufacturing city, which the cheap power furnished by the Niagara Power Company is expected to bring into existence.

The Cement Trade and Adulteration.—The cement trade recently held a meeting at the London Chamber of Commerce for the purpose of receiving and adopting or otherwise certain recommendations of the special committee which had been appointed to investigate and report upon the extent of the practice of admixtures with Portland cement and as to the justifiability thereof. The trade, with only one dissentient, adopted the recommendation of the committee that it was advisable that all manufacturers of Portland cement, who have used any outside material or materials in the manufacture of that article, should at once discontinue the practice. The use, however, of not more than two per cent. of gypsum, as practised by the German manufacturers for the purpose of regulating the setting of the cement, is considered optional. Messrs. Stanger and Blount, who are experts, have been instructed to report early in January, if possible, on the admixtures with Portland cement of the Thames and Medway, and the extent to which they are used.

Rack-railway in Japan. — Japan possesses a rack-railway, which is a connecting link in a main line, having more favourable ground for the other portions of its course, which is worked by ordinary locomotives. While, therefore, the stations of the rack-railway are for it terminal stations, they may also be regarded junction stations for the whole main line. The distance between these two points, measured horizontally, is five and a-half miles, but the actual length is, of course, somewhat more than this on the incline. Iron trough sleepers, inverted, are used to support the rails, and also to carry the rack apparatus, which has a double grip, and is placed in the centre of the track, which is single. A loop or bye-pass laid near the half length of the line, enables the trains to clear one another in mid-passage. The locomotives are all six-wheeled, coupled, having a diameter of 3ft. and furnished with cylinders 1ft. 3in. in diameter, and having length of stroke of 1ft. 8in. When in full working order, the locomotives weigh about thirty-six tons and carry some three tons of water, and over one ton of coal, and carry steam up to a pressure of 175 lb. A pair of cylinders work the pinions of the rack, which have a diameter of 1ft. 3in., and with a train weighing 100 tons, the usual speed does not much exceed five or six miles an hour. It is about two years since this little mountain line was opened for traffic, and it has been found to be of great service, and in all respects to work in a most satisfactory manner.

Royal Meteorological Society.—The monthly meeting of this society was held on Wednesday evening, the 19th inst., at the Institution of Civil Engineers, Great George-street, Westminster; Mr. R. Inwards, F.R.A.S., president, in the chair. Twenty-six new Fellows were elected. Mr. H. Southall, F.R. Met. Soc., read a paper on "Floods in the West Midlands," in which he gave an interesting account of the great floods which have occurred in the rivers Severn, Wye, Usk, and Avon. He has collected a valuable record of the floods on the Wye at Ross, which he arranges in three classes, viz.: (1) Primary or highest of all, those of 14ft. 6in. and above; (2) secondary, those with a height of 12ft. to 14½ft.; and (3) tertiary, those with a height of 10ft. to 12ft. The dates of the floods above 14ft. 6in. are as follows: 1770, November 16th and 18th; 1795, February 11th and 12th; 1809, January 27th; 1824, November 24th; 1831, February 10th; 1852, February 8th and November 12th. The height of the recent flood on November 15th, 1894, was 14ft. 3in., which was higher than any flood since November, 1852. The flood on the Avon at Bath on November 15th, 1894, is believed to have been the highest on record. Mr. R. H. Scott, F.R.S., gave an account of the proceedings of the International Meteorological Committee at Upsala in August last, with special reference to their recommendations on the classification of clouds and the issue of a Cloud Atlas. A paper by Mr. S. C. Knott was also read, giving the result of meteorological observations made at Mojanga, Madagascar, during 1892 to 1894.

## AMERICAN NOTES.

(*From our own Correspondent.*)

New York, December 14th.

More or less uneasiness exists in financial circles over the possibilities of large gold exportations. General trade is good, considering the season. In manufacturing lines the policy is still pursued of ordering only a little more than sufficient to fill orders. Compared to sixty days ago, production shows a decided increase, but railroad traffic, while improving, is not such as to strengthen confidence in better dividends. Pig iron is weak and dull. Buyers know production can be increased 20 per cent. and stocks expanded to a limit that might depress prices. Steel billets are 15·25 dols. at Pittsburgh, and rails 22 dols. Merchant iron and steel mills are working satisfactorily. Large orders for skelp, pipe, plate, and rods have been placed during the past few weeks, and manufacturers feel encouraged for the future. Users of every form of iron and steel are in need of supplies, but all buy only enough to keep going.

No radical legislation is probable this winter, but the country will feel safer when March 4th is past. The country has suffered enough for the politicians, and public sentiment now demands a cessation from all unnecessary agitation.

Conditions are favourable to a much larger consumption after the opening of the spring trade.

## LAUNCHES AND TRIAL TRIPS.

The Royalist, turret deck screw steamer, was launched from the yard of Messrs. William Doxford and Sons, of Sunderland, on the 13th inst., having been built to the order of Messrs. Angier Brothers, of London, and will receive the highest class in both the British Corporation and Bureau Veritas Registries.

On Thursday, December 13th, Sir Raylton Dixon and Co. launched from the Cleveland Dockyard, Middlesbrough, the fine spar-deck steamer Steinberger, which has been built to the order of the Hansa Steamship Company, Bremen. This is the fourth steamer Sir Raylton Dixon and Co. have launched for the same owners within eighteen months, and a fifth is now on the stocks. The principal dimensions are:—Length, 352ft.; breadth, 44ft.; depth moulded, 29ft. 7in., and she is built to Lloyd's highest class. The spar deck is of steel sheathed with teak, main deck of steel, and the poop bridge and forecastle decks are of teak. The steamer has a deadweight capacity of about 5500 tons, and web frames are fitted throughout the holds in lieu of hold beams. The accommodation for the captain, officers, and engineers is fitted amidships. The vessel will be fitted with Sidgwick's patent hinged topmasts, so that they can be readily lowered when required. Triple-expansion engines will be supplied by Messrs. T. Richardson and Sons, Hartlepool, having cylinders 21½in., 39in., and 57in., by 45in. stroke, with two large single-ended steel boilers working at 180 lb. pressure. The steamer, on leaving the ways, was named Steinberger. This vessel brings up the gross tonnage launched by Sir Raylton Dixon and Co. this year to 32,220 tons.

The Inchanga, the latest addition to Messrs. John T. Rennie, Son, and Co.'s Aberdeen line of steamers to Natal, was successfully launched from Messrs. Hall Russell's yard at Aberdeen, on the 14th inst. She is built from a fine model, having dimensions of 288ft. by 25ft. 9in., designed for high speed at sea. She will be fitted out with all conveniences for about fifty first-class passengers, with handsome saloons, ladies' saloon, smoking-room, &c., being lighted throughout with electricity upon the latest practice, to ensure safety and provide against accidental failure. Her deck machinery includes steam steering gear and windlass, and all needed machinery for quick handling of the ship and cargo. Messrs. Rennie's long experience in the Natal Colony has shown them what is needed in designing for the special service of their steamers, and they have been assisted by their consulting engineers, Messrs. Flannery, Baggallay, and Johnson, of London and Liverpool, who designed and have inspected the machinery during her construction. The vessel was named by Mrs. Hamilton, of Glasgow, sister to Mr. G. Rennie, and she took the water in the most successful and easy manner. She proceeded to the machinery quay to take in her engines and boilers. The former will have cylinders 24in. by 39½in. by 64½in. by 42in. stroke, driven by three powerful boilers at 180 lb. pressure of steam. Her auxiliary machinery will consist of independent sets of feed pumping engines, in addition to the usual feed pumps, feed heating and filtering machinery, evaporating and distilling machinery for boilers and passengers to provide hot and cold water, and the many necessaries in a steamer intended for special service.

Liverpool Engineering Society.—The fourth ordinary meeting was held at the Royal Institution, Colquitt-street, on Wednesday evening, the 5th inst., the president, Professor S. S. Hele Shaw, M. Inst. C.E., in the chair. The West premiums for the past session were presented to Messrs. Morgan and Duncanson. The remainder of the evening was devoted to the reading of a paper "On the Whirling and Vibration of Shafts," by Stanley Dunkerley, M.Sc., in which the author stated that a shaft, however nearly balanced, when driven at a particular speed, bends, and unless the amount of deflection be limited might even break, although at higher speeds the shaft again runs true. The particular or critical speed depends on the manner in which the shaft is supported, its size and modulus of elasticity, and the sizes, weights, and positions of any pulley it carries. The formulæ giving this speed have been worked out, for two simple cases with unloaded shafts, by Professors Rankine and Greenhill. A general theory applicable to all cases has been deduced by Professor Reynolds; and the author has obtained mathematical formulæ giving the critical speed in terms of the diameter and length of the shaft, weights and positions of the pulleys, &c., in the particular cases applicable to the different conditions under which a shaft works. The formulæ so obtained cover all cases which are likely to arise in practice, and the object of the present paper is to give those results in such a form that they can be applied directly to practice by engineers.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*4th December*, 1894.

23,580. Preservative Food Compounds, C. Stern, Liverpool.

23,581. Signal Apparatus, W. P. Thompson.—(*G. J. Schoeffel, United States.*)

23,582. Cycle Ambulance, W. P. Thompson.—(*D. Hönig, Germany.*)

23,583. Sand-blast Apparatus, J. E. Mathewson, London.

23,584. Colouring Matter Production, H. E Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)

23,585. Rendering Glue Insoluble, A. Zimmermann.—(*The Chemische Fabrik auf Actien vormals E. Schering, Germany.*)

23,586. Millstones, C. J. Potter, London.

23,587. Photographic Cameras, S. M. T. Amherst, London.

23,588. Furniture Polish, T. J. W. Lott, London.

23,589. Manufacture of Cocoa-fibre Brushes, W. P. Thompson.—(*J. G. Roth, Germany.*)

*5th December*, 1894.

23,590. Gas Batteries, H. T. Barnett, London.

23,591. Protecting the Legs of Cyclists from Rain, W. Stokes, Dublin.

23,592. Working Chemical Furnaces, G. T. Beilby, Midlothian.

23,593. Pneumatic Tires for Cycles, J. Silbermann, Glasgow.

23,594. Manufacturing Split Lifts, R. Kershaw and The Bristol Cut Leather Company, Bristol.

23,595. Method of Stopping Rabbeth Spindles, E. Sykes, Halifax.

23,596. Sewing Needle Threaders, E. S. Restieaux, Neath.

23,597. Securing the Doors of Cages, H. Kinsey and C. Maggs, Swansea.

23,598. A Roller Bearing, J. C. Stringer, Wincobank.

23,599. Cycle Wheels, J. W. and E. Fulwell, London.

23,600. Picking Motions for Looms, I. Jackson, Manchester.

23,601. Display Scoops, W. Parnall, Bristol.

23,602. Brace Fittings, C. N. Eyland, Birmingham.

23,603. Knitting Machines, R. Challands, F. W. Pare and J. H. Smith, London.

23,604. Supporting Shelves, J. C. Rimmington, London.

23,605. Fastener for Ships, W. Matheson, Hebburn-on-Tyne.

23,606. Peaked Flat-topped Caps, A. E. Horder, Bristol.

23,607. A New Nail, C. F. Rothé, Manchester.

23,608. Mounting of Metal Shells, J. Gregson, Preston.

23,609. Tramway Trucks, J. E. Wallis and Wallis and Steevens, Hants.

23,610. Draught Excluder, W. Walks, Bradford.

23,611. Mechanism of Pulley Blocks, R. Priest and W. Morrall, Birmingham.

23,612. Operating Haulage Winding Drums, T. Sorbie, Glasgow.

23,613. Automatically Opening of Road Doors, T. Sorbie, Glasgow.

23,614. Steam Motors, W. M. Walters, Liverpool.

23,615. Tandem Engines, W. M. Walters, Liverpool.

23,616. Pneumatic Wheels, W. H. Hanson.

22,617. Lamp Chimney, J. Lamb, Middlesbrough.

23,618. Steam Boilers, J. F. and M. Rankin, Glasgow.

23,619. Tuning Fork, J. H. Carr, Sheffield.

23,620. Driving-off Contents of Barrels, W. Platten, Sheffield.

23,621. Tobacco Pipes, D. Anderson, London.

23,622. Raising Curtains, F. Carter, Brighton.

23,623. Liquid Measures, J. Frankland, London.

23,624. Device for Detaching Horses, F. Zipperling, London.

23,625. Cushions for Billiard Tables, W. Defries, London.

23,626. Window Frames, D. Keith and W. McGeoch, Glasgow.

23,627. Paper Slitting Machines, D. N. Bertram, Glasgow.

23,628. Transmitting Signals, J. B. A. Légé, J. C. E. Carré, and M. L. Isaacs, London.

23,629. Carrying of Umbrellas, &c., A. Bolanachi, London.

23,630. Tobacco Pipes, &c., C. Mason and P. Mason, London.

23,631. Purifying of Wood Gas for Lighting, A. Greg, London.

23,632. Railway Signalling, W. Gray and C. M. Wawn, London.

23,633. Pressing Light Metallic Scrap, T. W. Ward, Sheffield.

23,634. Cycle Spanners, H. Jones, Birmingham.

23,635. Massage Apparatus, W. P. Thompson.—(*M. Goetze and H. Simons, Germany.*)

23,636. Pneumatic Tires, W. Stelfox and J. W. O. Walker, Manchester.

23,637. Spectacles and Eyeglasses, A. Brunner, sen., Liverpool.

23,638. Smoothing Irons, H. McKibbin, Manchester.

23,639. Arm Action Tricycle Mechanism, J. Munn, London.

23,640. Match Strikers, J. G. Glover, London.

23,641. Attaching Pneumatic Tires to Rims, J. Dring, London.

23,642. Machines for Decorticating Flax, G. E. Subra, London.

23,643. Boiling Water by Steam, F. W. Simmons, London.

23,644. Movable Bridges, T. W. Barber, London.

23,645. Earth Screws, T. W. Barber, London.

23,646. Surgical Tables and Chairs, H. G. Leisenring, London.

23,647. Vessel for Holding Two Liquids, M. Moore-Lane, Kent.

23,648. Photographic Cameras, J. Pearse, London.

23,649. Lugs for Tubes, F. H. Parkyn and J. Simmons, London.

23,650. Method of Dividing Angles, L. von Köppen, London.

23,651. Oil Engines, F. W. Kitto and W. Haworth, London.

23,652. Indicating the Position of Drowning Bodies, A. Belt, Hull.

23,653. Ice Cup, L. W. Tulloh, London.

23,654. Metal Clamp Binding Machine, J. Temler, London.

23,655. Matchbox, T. Remus, London.

23,656. Electric Heating Appliances, F. W. Schindler, London.

23,657. Padlocks, C. E. Schulte, London.

23,658. Restaurant and other Counters, N. Aubertin, London.

23,659. Self-acting Sheave, R. D. Glaister, London.

23,660. Delivering Coal on to Fires, J. F. Nicholls, London.

23,661. Electric Telegraph Instruments, J. Willmot, London.

23,662. Gas Retorts and Apparatus, J. Henderson, London.

23,663. Folding or Rolling Scale, J. W. Addy, London.

23,664. Velocipedes and other Vehicles, N. D. Pihet, London.

23,665. Lamps, S. Falk, London.

23,666. Cutting Tool for Lead Pipe, C. Fowler, London.

23,667. Trap for Beetles and Vermin, J. O. Spong, London.

23,668. Electric Impedence Coils, W. J. Davy, London.

23,669. Electro Depositing Zinc, The Cowper-Coles Galvanising Syndicate, Ld., and S. O. Cowper-Coles, London.

23,670. Composition for Preserving Fruit, W. O. Gilchrist.—(*A. Morris and J. A. Parker, Australia.*)

23,671. Treating Liquid Hydrocarbons, P. Dvorkovitz, London.

23,672. Tires, M. Adler, London.

23,673. Socks for Boots and Shoes, A. Graham, London.

23,674. Air Valves, H. Hadden, London.

23,675. Condenser Rollers, J. H. Robertshaw, W., J., and L. Hartley, London.

23,676. Saddle Clips for Cycles, J. F. Steele, H. V. Currie, and J. Jones, London.

23,677. Spring Bird Trap, J. and W. H. Walker, Birmingham.

23,678. Velocipedes, J. Fletcher, London.

23,679. Metallic Articles, La Société des Cuivres de France, London.

23,680. Electrolytic Copper, A. M. Clark.—(*La Société des Cuivres de France, France.*)

23,681. Thermometric Regulator Alarm, J. Dockree, London.

23,682. Operating Tramway Line Points, G. Gibbons, London.

23,683. Letter Cards, H. Jones, London.

23,684. Composing and Casting Type, G. A. Goodson, London.

23,685. Telegraph Poles, Siemens Bros. and Co. and W. Perry, London.

23,686. Packing Powdered Materials, F. Kraus, London.

23,687. Boot Protectors, P. Dews, London.

23,688. Galvanic Charging Elements, G. Platner, London.

23,689. Boilers, H. Postle Read, London.

*6th December*, 1894.

23,690. Leverage Gear for Bicycles, J. McKane, Belfast.

23,691. Pudding-bowl Fastener, J. Everett, London.

23,692. Non-slipping Pneumatic Cover, R. J. Stanley, Cardiff.

23,693. Garden Loop, W. E. Edwards, Stratford-upon-Avon.

23,694. Transfer Papers, J. Scott, Manchester.

23,695. Converting Bicycles and Tricycles, J. Parr, Leicester.

23,696. Order Transmitting Apparatus, W. Chadburn, Liverpool.

23,697. Construction of Electrodes, A. B. Woakes, London.

23,693. Bending Casks or Barrels, W. H. Tonkin, Stockport.

23,699. Construction of Shoes, F. Sternberg, Liverpool.

23,700. Crumb Sweeper, C. S. Pocock, London.

23,701. Starting Valve for Steam Engines, J. T. Dawes, Liverpool.

23,702. Cycle Gear, G. Taylor and C. D. Turrall, Coventry.

23,703. Cycles, F. Bowden, London.

23,704. Looms for Weaving Fire Hose, F. McClellan, Manchester.

23,705. Hair Curlers, R. Whitaker, Birmingham.

23,706. Riveting Metal Cisterns, &c., R. B. Waters, London.

23,707. Adjustable Wardrobe Hook, R. B. Waters, London.

23,708. Lehr for Annealing Glass, D. Moore, Newcastle-on-Tyne.

23,709. Fireplaces, W. Barraclough and A. Rhodes, Glasgow.

23,710. Removing Steam from Buildings, J. W. Taylor, Manchester.

23,711. Lenses for Optical Instruments, C. W. Parnell Cambridge.

23,712. Preventing Horses Slipping, G. Brown and A. J. Kearn, Charlton.

23,713. Printing Machines, W. H. and A. J. Dawson and J. Stott, Bradford.

23,714. Trunks and Bags, J. Waugh.—(*Amos and Co., Germany.*)

23,715. Method of Mounting Gas Burners, T. Redman, Bradford.

23,716. Driving Gear for Cycles, F. Brown.—(*H. Brown, Spain.*)

23,717. Lantern, B. Brockhues, Cologne.

23,718. Couplings for Railway Wagons, M. Walicki, Glasgow.

23,719. Heating Railway Carriages, W. Allman, Manchester.

23,720. Treatment of Skins and Leather, J. Hall, London.

23,721. Steam Traps, B. Blaiberg, London.

23,722. Cycles, G. Wishart and A. Jeffrey, Glasgow.

23,723. Casements, W. Youlten, London.

23,724. Assortment of Small Coal, W. C. Blackett, Durham.

23,725. Removing Mud from Cycle Tires, J. W. E. Peyton, London.

23,726. Magazine Fire-arms, M. C. Lisle and W. A. Berkey, London.

23,727. Permanent Way of Railways, H. Williams, Glasgow.

23,728. Braces, P. D. Lawson, Glasgow.

23,729. Mouldings for Picture Frames, W. P. Thompson.—(*W. Meyer, Germany.*)

23,730. Power Presses, C. Seybold and the Seybold Machine Company, London.

23,731. Cycle Rims, J. W. Fulwell and E. Fulwell, London.

23,732. Opening Postal Wrappers, H. E. Hudson, London.

23,733. Sprays, C. F. Slater, London.

23,734. Signalling, G. Lopes, London.

23,735. Pneumatic Tires, R. W. Huss, London.

23,736. Bedsteads, J. Cistez and G. Discher, London.

23,737. Controlling Supply of Oil, J. Dewrance, London.

23,738. Tube Cleaners, W. F. Bradbury, London.

23,739. Extracting Metals from Ores, J. Pfleger, London.

23,740. Metal Canisters, F. H. Breininger, London.

23,741. Designs for Textile Felted Fabrics, S. Sharp, London.

23,742. Hearthrugs, Mats, and Carpets, J. Lancaster, London.

23,743. Brooms, W. Sterkel, London.

23,744. Pneumatic Wheels, P. McCartan, London.

23,745. Electricity Meters, G. A. J. Telge, London.

23,746. Knife-machines, Hope-street Factory, Ld., and J. Laird, London.

23,747. Automatic Water Regulation, G. R. Martin, London.

23,748. Dynamo-electric Machines, F. M. Newton and T. Hawkins, London.

23,749. Spraying Machines, G. F. Strawson, London.

23,750. Tap, H. Gover, London.

23,751. Small-arms, H. W. Holland and T. Woodward, London.

23,752. Book Covers, W. Symons, London.

23,753. Holding Plush, G. F. Mathews, London.

23,754. Saddles, W. Robins, London.

23,755. Tongs, A. J. M. Simpson, London.

*7th December*, 1894.

23,756. Coin-freed Machine, J. F. and R. H. Shaw, Manchester.

23,757. Tires, R. J. Stanley, Cardiff.

23,758. Chairs, C. S. Bensted and G. Castleden, London.

23,759. Safety-pin, W. Beverley and J. C. Riddell, Glasgow.

23,760. Door Handles, H. F. Christie, Halifax.

23,761. Flower Pots, D. Tuley, Hatfield.

23,762. Cranes, F. W. S. Stokes, London.

23,763. Darner, M. J. Orphoot, Edinburgh.

23,764. Metallic Packings, G. W. Sutherland, Glasgow.

23,765. Bicycles, H. J. S. Ainsworth and W. Bradley, Halifax.

23,766. Smoke Consumer, W. McGlashan and J. P. Rawlings, Leith.

23,767. Rifle Black, W. D. Luff, Portsmouth.

23,768. Embossing Designs on Woven Fabrics, W. S. Boyd, Halifax.

23,769. Hypodermic Syringe for Dentists, P. B. Laskey, Glasgow.

23,770. Manufacture of Nails, A. George, Manchester.

23,771. Brakes and Foot-rests for Cycles, H. Holt, Grantham.

23,772. Comb, J. A. V. Baude, Derby.

23,773. Dressing Silk, H. Hoyle and E. Scarborough, Halifax.

23,774. Burners for Ignition Tubes of Motors, H. E. Kear, Bristol.

23,775. Bricks, H. R. Stockman, Dover.

23,776. Stirrups, H. Frost, Birmingham.

23,777. Latches, E. H. Warden and C. P. Bickin, Birmingham.

23,778. Brushes, R. Phillips, Halifax.

23,779. Egg-timers, C. W. Clark, Birmingham.

23,780. Fire-grates, J. Rigby, Sutton.

23,781. Gearing, W. Jackson, London.

23,782. Slates, S. B. Jackson, London.

23,783. Cycle Locks, W. J. Midelton, London.

23,784. Door Catches, W. J. Midelton, London.

23,785. Puzzles, N. O. Burns, London.

23,786. Book-markers, J. R. Eno, London.

23,787. Weighing Appliances, &c., W. B. Avery, London.

23,788. Apparatus for Churning, S. H. Wright, Liverpool.

23,789. Steam Generators, J. Thom, Liverpool.

23,790. Preventing the Bursting of Lead Pipes, S. Barwise, Derby.

23,791. Edge-setting Machines, H. A. Oldershaw, Leicester.

23,792. Securing Railway Rails, J. H. Lynde.—(*F. G. Lynde, India.*)

23,793. Valves for Steam Engines, C. R. Boswell, Kent.

23,794. Automatic Flushing Apparatus, A. J. Bond, Port Talbot.

23,795. Sanitary Closets, M. J. Adams, York.

23,796. Bodkin, W. Cook, Redditch.

23,797. Turning Leaves of Music, A. E. Hawks, Newcastle-on-Tyne.

23,798. Springs of Watches, &c., J. Hawley, Birmingham.

23,799. Domestic Hearthstands, W. H. Clews, Birmingham.

23,800. Feed-water Filters, W. J. H. Adam, Glasgow.

23,801. Steam Engine Indicators, D. Black and W. Stewart, Glasgow.

23,802. Oil Engines, G. Pollock and M. Whyte, Glasgow.

23,803. Strap Fasteners, G. H. and W. Thomson, Manchester.

23,804. Pneumatic Tires for Vehicles, W. Swain, Manchester.

23,805. Sorting Barm, M. Stenglein, Manchester.

23,806. Tires for Wheels of Vehicles, W. Pirrie, London.

23,807. Tube Joints, J. Brotherton, London.

23,808. Manufacturing Drain Pipes, B. Ames, London.

23,809. Key Rings, F. W. Grierson, Brighton.

23,810. Preventing Windows from Rattling, P. C. Hamilton, Loudon.

23,811. Brake for Cycles, E. W. Evans, London.

23,812. Adjustable Spanners, R. A. Day, London.

23,813. Broiling Apparatus for Bread, H. T. Poate, London.

23,814. Ventilation of Main Sewers, W. Mockett, London.

23,815. Manufacture of Cat-head Davits, W. Somers and E. G. Thomas, London.

23,816. Rotary Engines, W. P. Thompson.—(*W. C. Smith and H. P. Wheeler, United States.*)

23,817. Stays, W. B. Garniss, Liverpool.

23,818. System of Construction of Buildings, &c., A. F. Malgarni, London.

23,819. Surveyors' Adjustable Centreing-rod, C. Bristow, London.

23,820. Brakes for Cycles, A. H. Bond, London.

23,821. Material for Covering Surfaces, D. Marcus, London.

23,822. Framework for Carriages, D. Marcus and E. Horner, London.

23,823. Connecting Device, W. A. Lord, London.

23,824. Setting of Lithographic Stones, E. Bush, London.

23,825. Electric Arc Lamps, J. Brockie, London.

23,826. Gas Holders, F. Livesey and W. T. Sugg, London.

23,827. Pneumatic Tires, R. R. Gubbins, London.

23,828. Means for Propelling Cycles, H. Fleck, London.

23,829. Latch for Field Gates, S. Rolfe, London.

23,830. Tag Laces, J. S. V. Bickford, London.

23,831. Tobacco Pipes, W. Wall, London.

23,832. Railway Signalling, J. McGurk, London.

23,833. Securing Snaps of Bracelets, C. Dreyfus, London.

23,834. Apparatus for Firing Cartridges, H. Bonser and A. W. Bennett, London.

23,835. Dyeing of Lace, F. Hill, London.

23,856. Treads for Stairs, A. B. Soar, London.

23,837. Necktie Fastener, J. W. Jones, London.

23,838. Wort Cooler, H. E. Deckebach, London.

23,839. Flushing Apparatus, F. B. Hill and R. D. Brett, London.

23,840. Apparatus for Transporting Cash, N. Guthridge, London.

23,841. Clips for Bicycle Bells, C. Lohmann, London.

23,842. Buckles, A. H. Bugle, London.

23,843. Pocket Knives, J. T. Partington, London.

23,844. Couplings for Railway Vehicles, R. George, London.

23,845. Driving Gear for Cycles, W. Raimes, London.

23,846. Pulleys for Venetian Blinds, A. Ellwood, London.

23,847. Treating Sewage Sludge, Bacillite Sewage Purification Syndicate, Limited, and A. P. Hope, London.

23,848. Conveying Sewage Sludge, Bacillite Sewage Purification Syndicate, Limited and A. P. Hope, London.

23,849. Anti-fouling Paint, J. Holliday and A. Cameron, London.

23,850. Looms, G. Race and A. Wood, London.

23,851. Sheet-metal Cans, F. W. Durham and J. H. Moysey, London.

23,852. Cigarette Coverings, A. H. Sylvester, London.

23,853. Pasteurising Liquids, G. Gaertner, London.

23,854. System of Electrical Distribution, R. Wood, London.

23,855. Producing Magnetic Oxide, P. H. Bertrand, London.

23,856. Packing for Vessels, P. M. Justice.—(*M. W. Marsden, United States.*)

23,857. Apparatus for Moulding Pipes, W. Liehmann, London.

23,858. Measuring Electric Currents, F. H. Nalder, C. W. S. Crawley, and A. Soames, London.

23,859. Utilising Mineral Oils, W. S. Tailyour, London.

23,860. Rein-holders, A. Lipsky, London.

23,861. Ocean Steamers, P. Jensen.—(*T. Pringle, New Zealand.*)

23,862. Stoves, F. Balsamello, London.

23,863. Sabretasches, Wallets, &c., E. Doherty, London.

*8th December*, 1894.

23,864. Feed-bag for Horses, J. C. Meyers, Dublin.

23,865. Crushing Machinery, G. E. Sherwin, Birmingham.

23,866. Fog Signal, T. Thompson, Leeds.
23,867. Apparatus for Tilting Barrels, T. Bridge, Bolton.
23,868. Heeled Soles, W. C. Gilles, Beckenham.
23,869. Hydraulic and Pumping Engines, D. Johnston, Glasgow.
23,870. Velocipedes, W. J. Walford and T. T. Harrison, Bristol.
23,871. Cleaning Grain and Seeds, J. S. Cochran, Liverpool.
23,872. Rendering Fabrics Waterproof, W. Warburton, Stockport.
23,873. Slip Soles for Boots, R. A. Gardner, Newcastle-on-Tyne.
23,874. Propelling Cycles, A. R. Sawyer, Newcastle-on-Tyne.
23,875. Pneumatic Life Jacket, W. White, Cumberland.
23,876. Carts, J. Stenner, Bristol.
23,877. Ovens, J. T. Tompkinson and B. Butterworth, Rochdale.
23,878. Fuel-feeding Appliances, L. Burnet and S. Couper, Glasgow.
23,879. Preventing Persons Falling from Ladders, F. W. Golby.—(*E. Brucksch, Germany.*)
23,880. Blasting Minerals, M. R. Lawrence, Derby.
23,881. Tobacco Pipes, J. Colley, Staffordshire.
23,882. Construction of Furniture Castors, W. T. Eades, Birmingham.
23,883. Hose Pipes, F. Rowley, Manchester.
23,884. Linoleum Cork Carpets, J. Ingleby, Leeds.
23,885. Lamp Chimneys, H. M. Darrah, Manchester.
23,886. Lap Scutching Machines, W. Shore and J. Winterbottom, Shaw.
23,887. Fastening Boxes, C. Coomer, Bristol.
23,888. Window Sashes, J. Paterson, Glasgow.
23,889. Inkpots, J. M. Young, Glasgow.
23,890. Incandescent Gas Lamps, H. S. Kingston, Norfolk.
23,891. Seamless Inside Leg Pantaloon Hunting Breeches, W. G. Dyson, Leeds.
23,892. Quadruple Helical-pointed Bolt, M. A. Dubuc, France.
23,893. Metallic Bedsteads, J. and H. J. Brookes, Staffordshire.
23,894. Adhesive Stamps, &c., L. E. G. de Woolfson, Shrewsbury.
23,895. Cigarettes, A. C. Thomson, Glasgow.
23,896. Saddles, R. Mason, H. Gumbley, and P. L. Renouf, Birmingham.
23,897. Adjustment for Chains of Velocipedes, D. Dods, Paris.
23,898. Pneumatic Cab Tire, J. Whittall, London.
23,899. Tires for Road Vehicles, H. E. Smith, London.
23,900. Cuff Fastening, W. P. Thompson.—(*J. Koop, Germany.*)
23,901. Spring Clips and Axle Flaps, J. Farr, Liverpool.
23,902. Non-heat Conducting Coverings, S. Simon, Liverpool.
23,903. Machines for Clipping Hair, J. W. Newall, London.
23,904. Marking Soap, E. C. Lea and M. J. Gashion, London.
23,905. Manufacture of Bricks, &c., J. E. Stephenson, London.
23,906. Billiard Tables, W. Wood, London.
23,907. Apparatus for Sweeping Chimneys, J. P. Farnington, London.
23,908. Saws, F. G. Gwilliam, London.
23,909. Rulers, C. C. Brydon, London.
23,910. New Game, R. Walters, London.
23,911. Table for Billiards, A. R. Caudle, London.
23,912. Wheels for Traction Engines, S. P. Starsmore, London.
23,913. Infants' Feeding Bottles, T. J. R. Clarkson, London.
23,914. Holder for Infants' Feeding Bottles, W. S. Woodmancy, London.
23,915. Fastening Flowers into a Coat, E. A. Sherley-Price, London.
23,916. Fastening for Door Knobs, W. T. Ranson, London.
23,917. Bending and Shaping Sheet Glass, W. Cutler, London.
23,918. Construction of Fireproof Floors, T. Potter, Croydon.
23,919. Pressure Gauges, J. W. F. Warder and L. M. Luscombe, London.
23,920. Sewing Machines, D. Jones, London.
23,921. Steam Engine Valve Gear, G. A. J. Telge, London.
23,922. Busks for Corsets, Leggings, &c., F. M. Lehnig, London.
23,923. Slop Basin for Use with Tea Infusers, F. W. Bentall, London.
3,924. Painters' Pencils and Brushes, W. Sterkel, London.
23,925. Device for Stopping Wheels, &c., J. Wrede, London.
23,926. Kettles for Surgical Use, J. C. Richardson, London.
23,927. Derivatives of Hydroxyanthraquinone, H. E. Newton.—(*The Farbenfabriken vormals Friedrich Bayer and Co., Germany.*)
23,928. Thermometers and Barometers, J. Harrington, London.
23,929. Removing Boiler Scale, A. J. Boult.—(*W. H. Tebeau and W. J. Baker, United States.*)
23,930. Threshing Machines, V. Corbani, London.
23,931. Scuttle or Receptacle for Coal, E. Godfrey, London.
23,932. Obtaining Infusions of Coffee, W. Dray, London.
23,933. School or College Caps, R. C. Graham, London.
23,934. Folding Invoices, F. W. Lacey and G. H. Marshall, London.
23,935. Mining Machines, O. Imray.—(*J. A. Jeffrey, United States.*)
23,936. Electrical Fire Alarms, J. R. Shearer, London.
23,937. Grain Cleaning Cylinders, C. E. Mumford, London.
23,938. Ladies' Knickerbockers, R. Stapley and W. and H. Smith, London.
23,939. Light Narrow Gauge Railways, R. Harris, London.
23,940. Box for Cigarette Papers, F. J. Bell, London.
23,941. Cleaning Vegetable Fibres, S. Shorter and S. Stanbridge, London.
23,942. Clutches for Transmitting Power, C. and A. Edmeston, Manchester.
23,943. Golf Caddies, A. N. Charley, London.
23,944. Propelling Vehicles on Tramways, A. Diatto, London.
23,945. Tobacco Pipes, O. H. Cohen, London.
23,946. Water Gauges, J. A. and J. Hopkinson, London.
23,947. Cleaning Steam Boiler Tubes, J. Popper, London.
23,948. Playing Cards, P. Lehmann, London.
23,949. Weighing Machines, F. R. Simms and The Daimler Motor Syndicate, Ld., London.
23,950. Shut-off Valves for Engines, A. E. Olsen, London.
23,951. Printing, F. T. Felton and G. W. Bonney, London.

*10th December*, 1894.

23,952. Steam or other Engines, J. B. Johnston, Manchester.
23,953. Sanitary Combination, E. C. St. A. and E. Newby, Cardiff.
23,954. Forming Cylindrical Tenons, W. T. Robertshaw, Manchester.
23,955. Elevators and Fire Escapes, J. Youngson, Ontario, Canada.
23,956. Regenerative Furnaces, S. J. Robinson and S. Pope, Sheffield.
23,957. Rims or Fellies for Wheels, W. W. Stall, Birmingham.
23,958. Spoons and Forks, J. Maxfield and A. Staniforth, Sheffield.
23,959. Water Injector, J. Davies, Liverpool.
23,960. Traction Engines, F. J. Burrell, Thetford.
23,961. Steam-heated Evaporators, J. Weir, Glasgow.
23,962. Washing Machine Manufacture, J. T. Tullis, Glasgow.
23,963. Fastenings for Cuff Links, F. Griffith, Birmingham.
23,964. Wheel Hubs, W. F. Taylor and G. J. Philpott, Croydon.
23,965. Cycle Brakes, A. Duke, Cheltenham.
23,966. Movable Bath Lavatory Basin, D. McNish, Nottingham.
23,967. Stop and Wheel Valves, T. L. Davidson, Glasgow.
23,968. Mechanical Toy Cyclist, H. J. Hayes, Norwich.
23,969. Hooks and Eyes for Dresses, C. Crowther, Manchester.
23,970. Electric Conductor Supports, A. and J. M. Anderson, Glasgow.
23,971. Shearing Iron Bars, J. and H. W. Smith, Glasgow.
23,972. Watertight Doors, J. Chalmers and A. Aitken, Glasgow.
23,973. Method of Binding Books, R. C. Davies, Formby.
23,974. Thimble Pins, T., H. T., and J. Arrowsmith, Longport, Staffs.
23,975. Oil Stoves, F. S. Rippingille, London.
23,976. Pulley Blocks, Alldays and Onions Pneumatic Engineering Company, F. Lightbourne, and C. Gibson, London.
23,977. Steam Boiler and other Furnaces, E. Howl, London.
23,978. Watch Holder and Indicator, S. Lazarus, London.
23,979. Train Ventilating System, C. A. Erhart, London.
23,980. Sentinel Electrical Alarm, A. M. Morin, London.
23,981. Filling Aerated Liquid Bottles, J. McEwen, London.
23,982. Pocket Cigarette-making Machine, J. Moss, London.
23,983. Fruit Case, W. J. Kelley, J. W. Dorey, and G. F. Peek, London.
23,984. Fruit Case, W. J. Kelley, J. W. Dorey, and G. F. Peek, London.
23,985. Sunshade Holder for Cycles, M. Strohbach, London.
23,986. Preventing Bottles Overflowing, A. Ellis, London.
23,987. Axles for Vehicles, P. M. Justice.—(*La Société Charles Vermont, France.*)
23,988. Electric-lighting Devices, R. W. Inman, London.
23,989. Flushing Apparatus, W. H. Aitchison, London.
23,990. Racing Plates, W. J. Kent, London.
23,991. Horseshoes, W. J. Kent, London.
23,992. Typewriting Machines, B. Hoffmann, London.
23,993. Buttons, H. Goffey, London.
23,994. Decoration for Advertising Plates, B. Bradford, Liverpool.
23,995. Manufacture of Saponaceous Products, C. Weygang and The Petroleum Products Syndicate, London.
23,996. Manufacture of Artificial Fuel, C. Weygang and The Petroleum Products Syndicate, London.
23,997. Pedals for Cycles, E. Bolbrinker, London.
23,998. Tea-pots, T. D. Davies, London.
23,999. Controlling the Speed of Motor Engines, R. M. Macdonald, London.
24,000. Hand-saws, E. Benninghoven, London.
24,001. Waterproofing Boots, W. R. Searle, London.
24,002. Armatures for Electric Bells, I. H. Parsons, London.
24,003. Steam Boilers, E. Edwards.—(*E. Murbe, Germany.*)
24,004. Producing a Uniform Mixture of Air and Inflammable Vapour, E. Edwards.—(*L. Feil, Germany.*)
24,005. Carburetting Water-gas, A. G. Glasgow, London.
24,006. Gear Cases for Cycles, A. B. Soar and E. W. Collier, London.
24,007. Fire-grates, H. H. Lake.—(*J. Reagan, United States.*)
24,008. Chain Pumps, C. T. Burgess, London.
24,009. Production of Artifical Silk, F. Lehner, London.
24,010. Sockets or "Save-all" for Candles, F. Breese, London.
24,011. Screws, E. P. Cowcher, London.
24,012. Cycles, P. Fleuret, London.
24,013. Composition for Improving Soil, A. J. Thovoye, London.
24,014. Air-passage of Vent Taps, W. C. Alexander, Barnstaple.

*11th December*, 1894.

24,015. Purses for Delivering Coins Automatically, M. J. Jessop, London.
24,016. Toy Projectiles, C. E. Gyngell, London.
24,017. Cutting Textile Fabrics, J. J. Story and G. Blackburn, Nottingham.
24,018. Pump Clip, H. B. Newbold, Manchester.
24,019. Flexible Lever and Mud-guard Brake, L. Rushworth, Manchester.
24,020. Measuring Liquids, A. H. Reckless and W. Davenport, Derby.
24,021. Combined Terminal-box, &c., W. D. Reid, London.
24,022. Baitless Trap, J. Warburton, Ramsbottom, near Bury.
24,023. Cycle Stands, C. Allen, Birmingham.
24,024. Pressure-regulating Device, H. C. Longsdon, Keighley.
24,025. Umbrellas, W. Holland, jun., and J. W. Woodcock, Birmingham.
24,026. Desk, C. Mansford, Guildford.
24,027. Bathing and Sketching Tent, E. Rickard, Dublin.
24,028. Handles for Teapots, J. Meeson, Sheffield.
24,029. Coke Ovens, J. Dutson, Sheffield.
24,030. Sash Fasteners, S. C. Srawley, Birmingham.
24,031. Locomotive for Land or Water, C. Watkins, London.
24,032. Gas-meters, W. Alexander, Glasgow.
24,033. Steam Engines, W. D. Sherman, Glasgow.
24,034. Flours, E. B. Mitchell, Bristol.
24,035. Tires, W. McPhail, Wicklow.
24,036. Taps, A. Clifford, Dartford.
24,037. Making Ice, D. L. Holden and L. W. Serrell, London.
24,038. Roller Skates, F. I. Gibbs and W. Wright, Birmingham.
24,039. Roller Skates, F. I. Gibbs and W. Wright, Birmingham.
24,040. Knee-cap, J. Davies, Grimsby.
24,041. Sewing Machines, G. Benson and J. Kerr, Belfast.
24,042. Fog Signalling Apparatus, A. Stewart, Newcastle-on-Tyne.
24,043. Apparatus for Washing Barrels, C. L. Kline, Manchester.
24,044. Railway Chair, W. J. Ward, Newcastle-on-Tyne.
24,045. Recreation Railway, W. D. Pitt, London.
24,046. Nail-brush, E. A. Cunningham, Horsley, near Nailsworth.
24,047. Pianofortes, W. H. Dunkley, Birmingham.
24,048. Cycles, The Roulette Cycle Company and H. Cook, Coventry.
24,049. Substitute for India-rubber, J. Moore, J. Sampson, and E. T. Whitelow, Manchester.
24,050. Construction of Cycle Wheels, E. Vasey, London.
24,051. Greenhouse Light Lifter, A. W. Warren and C. Arnold, Waltham Cross.
24,052. Cycle Stands, E. Monkhouse, Bromley.
24,053. Shaping Dough, F. Dührkop, London.
24,054. Manifolding Sales Register, W. Assheton, D. Stewart, and C. J. Carroll, London.
24,055. Vehicle Wheels, E. G. Edmands and the Grappler Pneumatic Tire and Cycle Company, London.
24,056. Adjustable Level or Inclined "Floor," J. Barnet, Kirkcaldy.
24,057. Wringing Machines, E. Spannagel, London.
24,058. Stirrup, G. Martin, London.
24,059. Autoharps and other Instruments, C. Sucker, London.
24,060. Till, O. M. A. Davidson, London.
24,061. Reamers, R. H. Elliott and J. B. Carrington, Stockton-on-Tees.
24,062. Indicating Mechanism, B. Cawthorn and J. Brown, Stockton-on-Tees.
24,063. Obtaining Dry Manure, W. P. Thompson.—(*Wirth and Co., Germany.*)

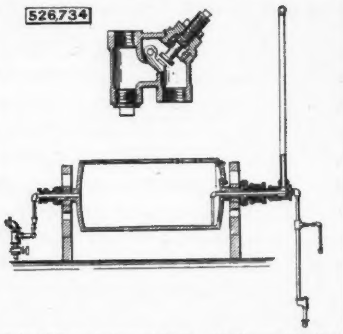
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**526,734.** Drying Cylinder, *A. G. Paul, Boston, Mass.—Filed January 22nd*, 1894.

*Claim.*—(1) The combination of a drying or heating cylinder with a discharge pipe connected with one of the journals thereof, and a trap consisting of a valve device at the lower end of the said discharge pipe, substantially as before set forth. (2) The combination of two or more drying or heating cylinders, separate discharge pipes, one connected with each cylinder, a trap consisting of a valve device at the outer end of each discharge pipe, a regulating device to regulate the amount of water that can be discharged from each discharge pipe, and a common drain pipe into which the discharge pipes empty, substantially as before set forth.

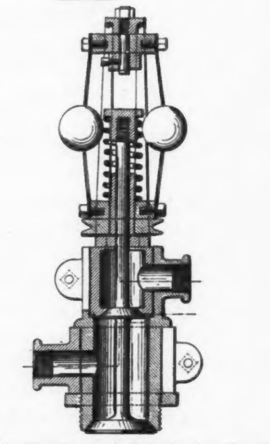
526,734



**526,837.** Gas Engine, *C. F. Hirsch, San Francisco, Cal.—Filed February 20th*, 1893.

*Claim.*—(1) In a gas engine, the combination of the gas inlet valve and the air inlet valve, both carried by a common stem and moving simultaneously therewith, a valve-supporting shell or chamber for each of these valves and split collars or shells embracing the aforesaid valve-supporting shells and having openings to coincide to a greater or less degree with corresponding openings in the valve supporting shells accordingly as the embracing collars are adjusted, together with adjusting bolts engaging lugs in the ends of the split shells, substantially as described.

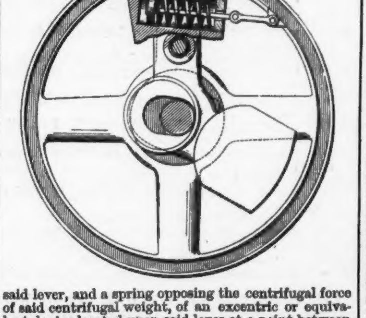
526,837



**526,856.** Governor, *R. C. Carpenter, Ithaca, N.Y.—Filed November 13th*, 1893.

*Claim.*—(1) In a governor the combination, with a fly-wheel revolubly mounted, a lever pivoted thereto at a point excentric to the centre of the fly-wheel, a centrifugal weight secured to one end of said lever, a counterbalance weight secured to the other end of said lever, and a spring opposing the centrifugal force of said centrifugal weight, of an excentric or equivalent device located upon said lever at a point between said pivot and said centrifugal weight, the centre of the excentric being out of line with said pivot and centrifugal weight, substantially as described.

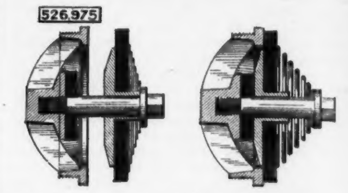
526,856



**526,975.** Pump Valve, *T. S. la France, Elmira, N.Y.—Filed September 27th*, 1892.

*Claim.*—(1) The combination of the valve seat having an outer bearing, a central bearing, and a pad or cushion on the said central bearing, the valve proper fitted to said outer bearing, the supporting plate under said valve proper and arranged to abut against the cushion of the central bearing when the valve is closed, such supporting plate being formed to nearly fill the port or valve space when the valve is closed, all substantially as and for the purposes set forth. (2) The improvement in valves herein described, consisting of the seat having an outer bearing, an inner or central bearing provided with a pad or cushion, the stem on which the valve slides, the valve proper, fitted to the outer bearing of the valve seat, the supporting plate under said valve proper, made to nearly fill the port within the outer bearing and arranged to abut against the pad or cushion of the central bearing when the valve is closed, all substantially as and for the purposes set forth.

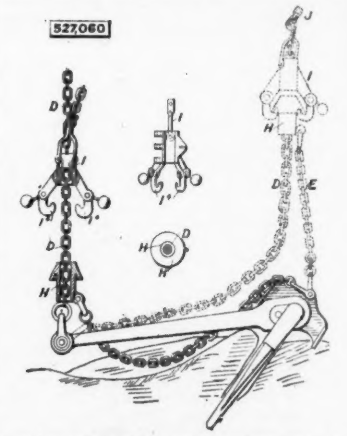
526,975



**527,060.** Means for Raising Anchors, *H. A. House and H. A. House, Jr., Bridgeport, Conn.—Filed November 25th*, 1893.

*Claim.*—(1) The means or devices for raising anchors by transferring the lifting point from the shackle end of the shank to the head or fluke end of the anchor, which consist of a sleeve sliding on the main cable, a chain connecting the said sleeve to the head or fluke end of the anchor and grappling apparatus adapted to slide on the main cable and to engage with the aforesaid sleeve combined, arranged and operating, substantially as described. (2) The means or devices for raising anchors which consist of a sleeve H free to slide on the main cable D and provided with a lip H′ adapted to be engaged by the hooks of the grappling apparatus, a chain or rope E connecting the sleeve H with the head or fluke end of the anchor, and grappling apparatus I sliding on the main cable D and provided with hooks I⁴ adapted to engage with the sleeve H, so as to connect the chain J with the chain E combined and operating, substantially as described.

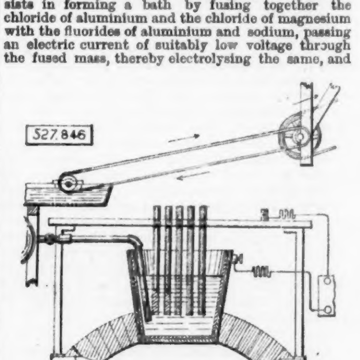
527,060



**527,846.** Process of Reducing Aluminium, *L. Waldo, Bridgeport, and F. A. Gooch, New Haven, Conn.—Filed March 23rd*, 1894.

*Claim.*—(1) As an improvement in the art of manufacturing aluminium, the herein-described process, which consists in forming a bath by fusing the chloride of aluminium and the chloride of an alkaline earth metal with the fluoride of aluminium and the fluoride of sodium, passing an electric current of suitably low voltage through the fused mass, thereby electrolysing the same, and supplying hydrogen to the bath, substantially as and for the purposes set forth. (2) As an improvement in the art of manufacturing aluminium, the herein-described process, which consists in forming a bath by fusing together the chloride of aluminium and the chloride of magnesium with the fluorides of aluminium and sodium, passing an electric current of suitably low voltage through the fused mass, thereby electrolysing the same, and supplying hydrogen to the bath, substantially as and for the purposes set forth. (3) As an improvement in the art of manufacturing aluminium, the herein-described process, which consists in forming a bath by fusing together the chloride of aluminium, the chloride of an alkaline earth metal and the chloride of sodium with the fluorides of aluminium and sodium, passing an electric current of suitably low voltage through the fused mass, thereby electrolysing the same, and supplying hydrogen to the bath, substantially as and for the purposes set forth. (4) As an improvement in the art of manufacturing aluminium, the herein-described process, which consists in forming a bath by fusing together the chlorides of aluminium, magnesium, and sodium, and the fluorides of aluminium and sodium, passing an electric current of suitably low voltage through the fused mass, thereby electrolysing the same, and supplying hydrogen to the bath, substantially as and for the purposes set forth.

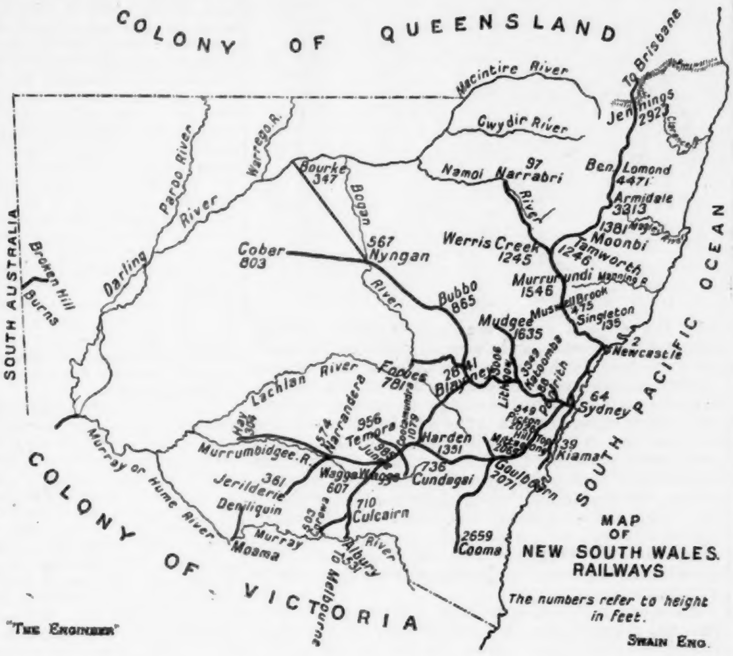
527,846



Throat Irritation and Cough.—Soreness and dryness, tickling and irritation, inducing cough and affecting the voice. For these symptoms use Epps's Glycerine Jujubes. In contact with the glands at the moment they are excited by the act of sucking, the Glycerine in these agreeable confections becomes actively healing. Sold only in boxes, 7½d.; tins, 1s. 1½d., labelled, "James Epps and Co., Homœopathic Chemists, London."

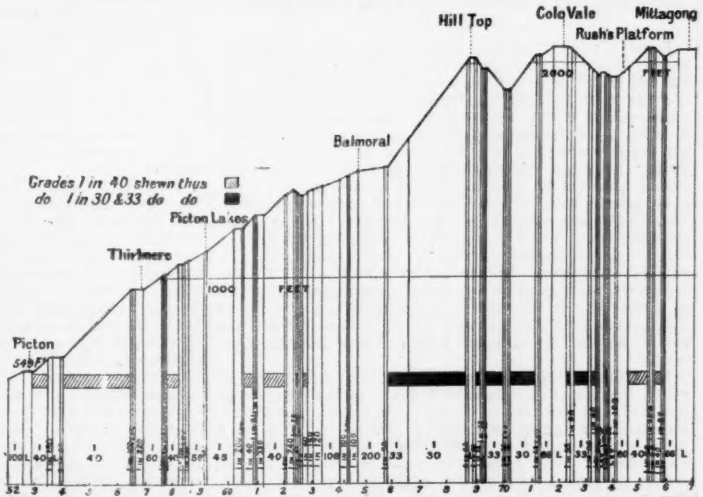
## THE RAILWAYS OF NEW SOUTH WALES.

Very little seems to be known in this country about the railways of our Colonies, judging from articles and letters appearing from time to time in our newspapers. For instance, the *Morning Post*, in a leading article in its issue of October 26th, makes the following statement:—"Perth, Adelaide, Melbourne, Sydney, and Brisbane are now joined together by railways." Now there is no railway between Perth and Adelaide, the country between these two cities is practically a desert, and it will be many years before a railway will be built joining these capitals. At present the quickest way to get from Adelaide to Perth is by steamer, a three days' trip across the Australian Bight, to Albany, and thence by rail to Perth. Many such misleading statements have appeared from time to time, so a short account of the railways of one of our most important Colonies may not be amiss.



The railways of New South Wales, unlike those in this country, are owned and worked by the Government. The conditions there were so different that everything pointed to the advantage of State ownership of railways, and the Government have, in many cases, adopted the very sensible plan of building lines to open up the country, not waiting, as a private company would have to do, until the line would pay at once for the making; the consequence is that much of the country has been opened up by lines that have not paid in the past, and some that are still worked at a loss, but which should in the future prove paying concerns and add much to the revenue and prosperity of the Colony.

The three Colonies on the east coast of Australia, namely, New South Wales, Victoria, and Queensland, have adopted the suicidal policy of each building its lines of a different gauge. New South Wales has the standard gauge of 4ft. 8½in., Victoria 5ft. 3in., and Queensland 3ft. 6in. In the case of the latter it was to some extent excusable, as it has a large extent of country sparsely populated, and therefore could not afford to build long lengths of line of broad gauge, so preferred to construct more line of the cheaper narrow gauge rather than build less of the broader. But it is impossible to understand why New South Wales and Victoria should have constructed their lines of a different gauge; the difference in gauge is so little, and the difference in cost so small, that well knowing, as they must have done in the beginning, that their lines must meet in the near future, it seems little short of madness on their part to have adopted different gauges. The discomfort and folly of this is keenly felt now the railways extend in a continuous line from Melbourne to Brisbane. It means that there can be but little through goods traffic, as the cost is largely augmented by the enforced transhipment at Albury — the junction of the New South Wales and Victorian lines— and great discomfort is caused to passengers between Sydney and Melbourne, who at Albury are turned out on to a bleak platform at 5.45 a.m., to have their hand baggage examined by the Victorian customs officials, and to change into the Victorian train. This is the most keenly felt by those who have availed themselves of sleeping accommodation.



PROFILE OF SOUTHERN LINE.

But to return to the South Wales railways. A few years back they were in a very bad state in every way, and were managed politically, one of the worst evils that can befall a railway system. In 1888 this was changed, and three railway commissioners were appointed. Mr. Eddy, the chief commissioner, came from the Caledonian Railway in this country, and since he took charge the railways of the Colony have undergone a complete change, and instead of being, as before, badly equipped and badly managed, have become a railway system of which any new country might well be proud.

The line between Sydney and Hornebush—eight miles —has been quadrupled, and all the stations on this section have been rebuilt, large portions of the lines have been relaid and reballasted, and in all cases where renewal of the rails is required, T rails of steel, 80 lb. to the yard, are being laid. This 80 lb. steel rail is now the standard rail of the Colony—the others up to the present in use are 70 lb. and 75 lb. iron, and 71 lb. and 75 lb. steel. Chairs are not used, the rails being spiked direct to the sleepers, which are of a very hard and durable wood— —ironbark—split and adzed to size, and not sawn, thus securing timber straight in grain. These sleepers weigh nearly twice as much as the pine sleepers used in this country; they are spaced 2ft. 7in. centre to centre, and 1ft. 8in. at the rail joints. The grades in many instances are very heavy. On the western line from Penrith—thirty-four miles from Sydney—to Katoomba—sixty-six miles from Sydney—there is a rise of 3261ft. in the thirty-two miles, there being a short distance out of Penrith a stretch of 1 in 30, and between Penrith and Katoomba about twelve miles of 1 in 33, the sharpest curve being eight chains radius.

On the southern line, between Picton and Hilltop, there is a rise of 1477ft. in sixteen miles, there being a stretch of two miles in one place of 1 in 30, and several miles of 1 in 33 and 1 in 40; the sharpest curve is of 16 chains radius.

On the northern line, between Moonbi and Walcha Road, there is a rise of 2005ft. in twenty-eight miles; and between Tamworth and Ben Lomond, a distance of 119 miles (including the last-mentioned incline), a rise of 3225ft., the height of Ben Lomond station being 4471ft. The sharpest curve is of 12 chains radius.

From the foregoing it will be seen that the haulage is of a very heavy nature on the New South Wales railways, requiring large locomotives of great pulling power. In former times two engines were generally used, but in order to reduce expense and to meet the demands of heavier traffic, the following locomotives were ordered from the Baldwin Company, U.S.A., in 1891: Twelve 10-wheeled bogie passenger engines of 90 tons 7 cwt. in working order, with six coupled wheels 5ft. 1in. in diameter—the centre pair without flanges—and twenty 10-wheeled goods engines, 94 tons 12 cwt. in working order. These have eight wheels coupled 4ft. 3in. in diameter, the two centre pairs without flanges, and a two-wheeled truck. These locomotives were ordered from America because they were wanted badly and the English makers could not deliver them in time. At first they were not quite up to the mark, but, when altered, proved satisfactory, hauling trains over the inclines which in former times were always drawn by two engines, they have much reduced the cost of haulage. At a later date some fine 10-wheeled bogie passenger engines were procured from Messrs. Beyer, Peacock and Co., with six wheels coupled 5ft. in diameter, 88 tons 7 cwt. in running order, as well as some powerful 8-wheeled suburban tank engines from the same firm. The latter have proved very useful for the large suburban traffic which has grown during the last few years.

The carriage stock has also been greatly improved of late, the new vestibule cars on the Sydney to Melbourne service, over 70ft. long, on six-wheeled bogies, ranking among the finest and easiest-running carriages in the world. The ordinary passenger coaches recently built are also good, and are in many cases fitted with lavatory accommodation. There are only two classes, first and second, on the New South Wales railways. With regard to the goods rolling stock, it has received considerable attention. The new 10-ton trucks with steel frames may be mentioned. Most of the goods rolling stock is fitted with spring buffers. The Westinghouse brake is used on all passenger trains; and here another anomaly crops up, for Queensland has adopted the vacuum brake—so that if the difference in gauge should be overcome in the future, there would still be the drawback of two systems of brakes to contend with. One would have thought that, after the lesson learned in this country on this subject, and the great extra cost and trouble caused on this side, all through stock having to be fitted with both kinds of brake, it would at least have had the effect of causing all the Colonies to adopt one standard brake.

Now let us turn to the train service and the speed of the best trains. New South Wales has 2500 miles of line, the greater part, of course, being single. The fastest and best equipped train is the Melbourne express, which leaves Sydney at 5.15 p.m. every day except Saturday, running to Mittagong, the first stop, seventy-seven miles, in 2 hours 43 minutes—28·34 miles per hour. This appears to be very slow running, but the fact of Mittagong being 2000ft. above Sydney must be taken into consideration. The corresponding express in the opposite direction covers this distance in 2 hours 6 minutes, including stop for collecting tickets—which is at a rate of 36·6 miles per hour. The distance from Sydney to Melbourne is 576 miles, and the express runs this in 18 hours 33 minutes, including over two hours of stoppages—which is a trifle over 31 miles per hour. There are twenty stops, two being of twenty-five minutes each and four other stations at which the train may be stopped by signal. Vestibuled sleeping-cars are run on this train at an extra charge on the first-class fare of 12s. 6d. for a lower and 10s. for an upper berth. The first-class fare is: Single £4 1s., return £6 1s. 6d.; and second class, single £3 0s. 8d., return £4 11s.

The service from Sydney to Brisbane is not so important as that to Melbourne, nevertheless the express is a creditable train, leaving Sydney each day, except Saturday, at 6.15 p.m., arriving at Jennings—the Queensland border—491 miles from Sydney, at 11.30 a.m. next morning, and at Brisbane 10.50 p.m., a distance of 723 miles in 28 hours 35 minutes, equal to 25·36 miles per hour, including thirty-four stops and thirteen other stations at which the train may be stopped by signal.

From the above it will be seen that, although not coming up to the English standard of expresses, these trains are very creditable, taking into consideration the number of stops, the heavy nature of the grades, and sharpness of curves, and that, except for a short distance at either end, they are running on single line.

The scenery along the lines is in several places very beautiful, the grandest is on the Western line through the Blue Mountains from Penrith to Lithgow, also between Sydney and Kiama on the south, and between Sydney and Newcastle on the north. On this section the line crosses the Hawkesbury River by the Hawkesbury Bridge, the largest in the Colony, and which is noted more especially for the difficulty experienced in getting a good foundation, the cylinders in the case of one pier having to pierce 170ft. of mud. It is near the bridge that the scenery is finest on this section.

The time has now come when the want of railway communication between North and South Sydney is felt, the great difficulty being that the point where a railway would be required to cross the harbour is about the busiest part, and much used by the largest ships, which would necessitate a high-level bridge or tunnel; the latter would perhaps be preferable, but the harbour is very deep at this point. In the course of a few years either one or other must be built, and whichever it is it will be a great undertaking.

Two short sections of the New South Wales railways occupy the somewhat unique position of acting as feeders for the railways of other Colonies, namely, the line from Deniliquin joining the Victoria line at Moama, and the line from Broken Hill, which joins the South Australian line at Burns. Strange as it may appear, the quickest and easiest—in fact, the only practicable way to get from Sydney to Broken Hill, one of the largest and most important mining centres in the Colonies, is by rail *viâ* Melbourne and Adelaide. No doubt in the near future a line will be opened up from Sydney to Broken Hill, which will divert to Sydney a great deal of traffic which is at present carried over the South Australian line to Adelaide. As will be seen from the railway map of New South Wales, there are three lines which might be pushed on to Broken Hill; but the northern line from Cobar is the most likely. Whichever route is chosen will open up much country which at present has no railway communication. We have said enough to give a fair general idea of the railways of the Colony. Much of interest has of necessity been omitted, owing to want of space; but this short account will show that New South Wales possesses a railway system worthy of so important a Colony. C.

---

The U.S. torpedo-boat Ericsson continues to break down. Two weeks ago we reported her fourth failure. Her fifth occurred on November 30th, owing to the low-pressure piston-rod giving way, wrecking the low-pressure cylinder and necessitating a long delay for repairs.

## ACCIDENTS ON PUBLIC ELECTRIC SUPPLY MAINS.

The attention of all engineers interested in the public supply of the electric current must have been attracted very strongly to the consideration of the present methods of installation of electric conductors. During 1894, and the latter half of the year 1893, a number of accidents happened which were caused by imperfect systems of electric conductors, or in which the imperfection of certain electric conductors was one of the secondary causes of the accident. The bulk of the accidents which have occurred in connection with the electric supply mains have been caused by the presence of coal gas in the conduits or inspection boxes, by a leakage of electric current, or by both these causes jointly.

Two well-defined systems of laying electric conductors exist: (1) The system of bare copper strip conductors, carried on insulating material fixed in built conduits. (2) The system of insulated conductors laid in the earth, or drawn into pipes of metal or of some composition. The first system is only applicable to low-pressure direct-current supply, while the second may be used for either direct or alternate current installations. Various theories were propounded before the facts of the cases were well understood. According to one theory, the water was liable to leak into the conduits specially built for bare conductors, and electrolysis took place, the hydrogen collected, and might be exploded in the air by a spark. Another theory was, that if a conductor became partially severed an arc might be formed, which would heat the air in a junction box to so high a temperature as to cause the upheaval of the lid with a report. Either of these explanations are quite thinkable, as Mr. Herbert Spencer would say; but so far as we are aware, neither agrees with the actual facts of the cases, as obtained by subsequent investigation and examination of eye witnesses.

We believe that in all cases where an explosion in a junction box has occurred, it has been caused by the application of a light to an explosive mixture of coal gas and air. Other accidents which were not attended with explosions were caused by leakage of the electric current to earth. In Norwich there was an explosion caused by an accumulation of coal gas. A similar one occurred in Sloane-square. Four explosions took place in Glasgow in the six weeks ending December 29th, 1893; the last accident injuring three men. A serious accident occurred at Bournemouth on February 8th, 1894, when a horse was killed, as noticed in our issue of 2nd March, 1894, and subsequently there have been several accidents in London which culminated in the Cannon-street explosions, described on page 451, 23rd November, 1894.

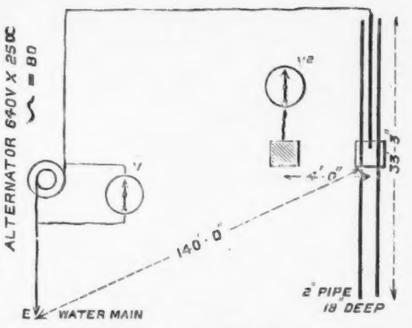
The Board of Trade have caused an inquiry to be made in each of the more recent cases as to the causes of the accident; and Major Cardew found in the case at Bournemouth that the insulation of a certain cable of seven No. 21 gauge wires was insufficient, the india-rubber being only $\frac{1}{20}$in. thick for a pressure of 2000 volts alternating current. He, therefore, advised that the insulation should in future consist of india-rubber of at least 0·1in. thick; and that inside junction boxes the cables should be covered with either lead or iron, and that this metal should be put into good electrical connection with the iron pipes into which the cables were drawn, so that there should be good earth connection of the pipes throughout the entire system.

Last January it was thought very surprising that a horse could be killed by an electric shock caused by leakage from the street mains while the horse itself was apparently standing upon the ordinary surface of the road, but the very similar accident in Cannon-street proves that the danger is a very real one.

After the Bournemouth accident Major Cardew decided to make some careful experiments in order to determine what difference of potential could exist on the surface of the ground between two points about 4ft. apart when a leakage of electric current was taking place about 18in. below the surface. At Bournemouth the leakage was found to have taken place from a fault in an insulated main placed in an iron pipe 32ft. long and 1½in. external diameter. The pipe was not in metallic connection with the remainder of the pipe service, and its ends were fairly insulated as they were let into brick and cement walls, while the rest of it was in good connection with the earth. Experiments were carried out by Major Cardew and Major Bagnold at St. Mary's Barracks, Chatham, and the results were reported in the form of a paper communicated to the Royal Society by Lord Kelvin, and printed in the "Proceedings," vol. 56.

In order to repeat the conditions as nearly as possible, a length of 33ft. 3in. of 2in. iron pipe was buried to a depth of 18in. A piece of 37 strand, No. 16 gauge cable, was inserted in the pipe, so that the ends of the conductors made good contact with the inside of the pipe at its centre point. Over the centre of the pipe two 56 lb. weights were placed on the surface of the ground, and at a distance of 4ft. laterally another pair of 56 lb. weights were similarly placed; these represented the feet of a horse. A 16 kilowatt alternator was connected by means of an underground cable laid in stoneware pipes to the piece of cable in the 2in. pipe. The arrangement is shown in the cut, where V and $V_2$ represent voltmeters. The other pole of the alternator was connected to the 1½in. service pipe in connection with the barrack water mains. One end of the service pipe was in connection with a hydraulic ram, set in the ground at a distance of 140ft. from the centre of the buried pipe.

An 800 volt Thomson static voltmeter V was connected across the terminals of the alternator, and a pair of well insulated leads were attached by means of screws to the two pairs of weights situated over the buried pipe. These leads were run back to the experiment-room, and were connected alternately to a 140 volt static voltmeter and a Cardew voltmeter. As the earth resistance was rather low, the alternator could not be run up above 400 volts without overheating the armature. The results showed a potential difference between points 4ft. apart on the surface of over 20 per cent. of the whole potential difference used to charge the pipe when measured statically, and even when a current of nearly 0·1 ampère was drawn from the ground through a Cardew voltmeter, the potential difference was more than 10 per cent. of the whole. The frequency was about eighty periods per second. Another set of tests was then made. The soil in which the pipe was buried was loamy, and when digging the trench no worms were noticed; but towards the conclusion of the experiments it was noticed that hundreds of worms came to the surface, between 3ft. and 9ft. on either side of the pipe. No worms, however, appeared immediately over the pipe. In this experiment the weights were placed in a row, the first weight over the pipe, and the others in a line at right angles to the pipe, and 4ft. 5in. centre to centre.



In the original paper the authors have carefully tabulated their results, and the experiments on the whole show conclusively that under very different conditions of weather and amount of moisture in the soil, it is possible to produce a fall of potential energy amounting to 25 per cent. of the whole pressure in the supply between points on the surface of the ground 4ft. apart, a distance which most horses stand over; and further, that although the connection of such points by a conducting body naturally reduces this potential difference, yet when this conductor has about the resistance of a horse, say 400 ohms, sufficient current will pass to give a severe shock. The authors add that they hope to make further tests with pipes buried to greater depths, and with direct current as well as alternating current.

There can, however, be no doubt that one of the most essential requirements in a supply station is that there should be a trustworthy system of testing for leakage, and that tests should be made at short intervals; and, besides this, some thorough system of ventilation is, in our opinion, required to keep the conduits or pipes clear of the explosive mixtures of air and gas which are liable to be present. Infiltration of gas seems hardly a sufficient cause to account for the quantities of gas found in some boxes, as in that at Dowgate Hill, where 12 per cent. of gas was found to be present. It is probable that the gas pipes are fractured or joints loosened by the settling of the ground, and that in some cases connection is made between such leaks and the electric conduits direct. A system of mechanical ventilation seems called for, as somewhat tall columns would be required to induce a sufficient current of fresh air to flow through the pipes.

## ABSTRACTS OF CONSULAR AND DIPLOMATIC REPORTS.

*Denmark: North Sea and Baltic Canal.*—The conclusions arrived at in a recent Danish pamphlet, entitled "The North Sea and Baltic Canal and the Free Port of Copenhagen," are that the canal is being constructed principally for military purposes, and it will not be of any commercial importance in relation to the Baltic trade. German authorities show the dangers attending the navigation of the Elbe, which during the winter months will be increased by frequent obstruction. On the other hand, there are two routes open to ships passing north of the Skaw on their way to the Baltic, viz., the Sound and Great Belt, both being very seldom closed simultaneously, and the dangers of navigating them being very much exaggerated, whereas the Elbe is closed during a part of each year. In the twenty winters—1871-91—the Sound was only closed for any considerable period during two of them. In the very severe winter of 1892-3, the Sound was closed by ice for a long period, but navigation was stopped at Kiel for an equal length of time from the same cause.

In examining the question of distance saved by using the canal, the island of Barnholm is taken as the terminus at one end and the port of Dover at the other. The saving, according to a German estimate, is 200 miles. This, at a speed of from nine to ten miles an hour, gives a saving of about twenty hours, from which must be deducted nine to ten hours caused by using the canal at a reduced speed. The result is that, from the most southerly port, Dover, under circumstances so favourable as to be hardly ever realised, the saving by using the canal is ten hours, the profit on which would be less than the canal dues. From the east coast of England, West Hartlepool, Newcastle, Sunderland, whence a very considerable part of the coal for the Baltic is exported, according to a German authority the saving is ninety miles. Whereas the Danish contention is that by following the same calculation as the preceding, the new route takes longer time than the old. From Scotch ports—Methill, Grangemouth, Burnt Island, and Leith—whence the voyage is supposed to be forty miles, and with Moën for a terminus, eighty-three miles shorter, the saving by going north of the Skaw is very considerable, which must also be the case with ships passing north of Scotland. The free port of Copenhagen, now in course of construction, will be accessible to ships drawing over 31ft., and navigable during the whole of the twenty-four hours nearly all the year round, while Hamburg and Bremen are about seventy and fifty-six miles respectively from the mouths of the Elbe and Weser, which are impassable by tide for half of the twenty-four hours, and are often subject to ice obstructions, with comparatively slight frosts. With a view to encourage the entry of shipping, the Danish Government have decided to reduce the dues on the free port of Copenhagen, so as to make it one of the cheapest instead of, as at present, one of the most expensive ports. The port and other charges for a steamer of 1000 tons register, inward and outward, amount to £74 12s. 3d. In the free port they will be reduced to £14 0s. 5d.

*Belgian patent designs.*—The United States Consul at Ghent reports:—The Belgian law now in force provides that all plans, designs, and models of patented articles deposited in view of securing an exclusive privilege shall be kept in secret unless litigation arises in respect to them owing to this secrecy. Many persons may be working to invent some article which is already patented, but of whose details they have no knowledge. A great hardship is thus inflicted upon those who only at the completion of their task learn that some other person has already the exclusive right to manufacture and sell the special article invented anew.

*Germany: Consuls and trade of.*—The United States commercial agent at Bamberg reports:—The ceaseless efforts of the representatives of German industries to open up new fields for the sale of their products has received special encouragement and support from the German Government since the holding of the World's Columbian Exposition. German consular officers in foreign countries are devoting themselves to advancing the interests of German industries by employing a novel but thoroughly practical method of securing sources of demand for German manufactures. Through the German Consuls in the United States, agencies have been established at nearly all the important centres, in charge of persons conversant with both English and German, and thoroughly furnished with information relating to the exporting industries of their country. At these bureaus interested parties can obtain advice and information as to German sources of supply, and the relative condition of market prices, freight rates, and tariff duties, so that, benefiting by this, the importer of even small quantities will in future be able to order goods from Germany at first hand. Such bureaus of information, if entrusted to the direction of the right persons, will in time prove to be of inestimable value to all interested. The otherwise wide-awake representatives of American industries could—as has often been urged in Consular Reports—profit by the examples of their German colleagues.

The British Vice-Consul at Kiel, in a recent report on the trade of that district, observes:—The conclusion to be drawn from a study of the statistics as to commerce and trade of Germany, as represented by its leading seaport, is that in the future Germany will not fail—and especially as new markets are developed—to extend her mercantile interests through her own enterprise, one of the factors of which is that German emissaries are either sent or go abroad liberally, and subsequently establish a trade for themselves or their principals. In the former case where this has been, they return home with the gains of their industry, from thence to proceed with their labours. It behoves my countrymen to realise this, and to see that they do not, from a false feeling of superiority, fall behind in the competition, or the day of awakening may come too late. The deduction to be drawn from the facts in this report is that they are not of a congratulatory nature, if it is considered that our commercial welfare is to a large extent dependent upon the maintenance by Great Britain of its position as the great carrying nation of the world. It is a common complaint with British seamen that British vessels are now filled with foreign seamen. The fault is purely their own, and the remedy lies only in their hands. It is a most difficult thing to ship British seamen here, because shipmasters prefer Germans and Scandinavians. They acknowledge the superiority of their own, and that when in difficulty or danger they prefer to have a British crew at their backs; but the chief cause of preference for the Germans and Scandinavians is their superiority in order and sobriety. There is a great improvement among our seamen compared with twenty or twenty-five years ago, better education and training ships having effected a good deal, but the British seaman has only himself to blame if foreigners take his place.

Not a tithe of the pains is devoted by my countrymen to ascertaining the commercial needs and tastes of the rest of the world with which they trade as is given by the Germans. The latter endeavour to find out the wants and consult the taste of their customers, while the former thinks such details outside his consideration, being confident that his manufactures are superior to all others. They are good, but convenience, fastidiousness, and other details which seem of little importance, are studied by German exporters and manufacturers.

The British Consul-General at Hamburg, in a later report, observes:—The principal fact shown by a review of the past year is the general lack of prosperity. In looking for the cause, it must be sought for more at home than abroad; and it is not far to seek. To the difficulties arising out of the interruption of the supplies of fuel, more than to anything else, is assigned the cause. This still largely hampers, if it does not wholly keep down, any improvement or revival in industries and trade generally. Another prominent fact is that the Germans are every year doing more carrying for themselves. This is apparent from a study of the figures of the British imports. Where there is a decline in certain articles it is because more of them are carried direct in German vessels than formerly. A word of warning to those interested at home! At present and in the future it will be found that strikes in the coal industry have alienated important customers and wholesale trade from the home collieries—trade which has never belonged to any but ourselves, and which has now, thanks to ill-judged counsels, passed for ever out of our hands, and which not all the agitators or strike leaders in the United Kingdom will ever succeed in recovering.

*Germany: Improvements of River Weser.*—Much has been done of late to improve the navigation of the Weser, with the result that sea-going ships, drawing from 15½ft. to 17½ft. of water, to Bremen Docks. Steamships of the North German Lloyd line navigate the river up to Bremen, one 311ft. long and 2571 tons register, steamed up in ballast, specially with a view to tell whether a vessel of her length could navigate the many turns in the river, the experiment being successful. The other, a steamship of 2334 tons, came up with the greater part of her cargo, and drawing 17ft. 5in., entered the Bremen Dock. The tonnage of sea-going vessels entering the city dock was in 1890, 173,404 tons; in 1891, 317,006 tons; in 1892, 433,164 tons; in 1893, 521,607 tons. The enlargement of the principal dock at Bremerhaven rendered necessary by the increasing size of the North German Lloyd's steamers, is progressing rapidly, and is likely to be completed in three years, so as to make ships of 32ft. draught to enter. The lock chamber—656ft. 2½in. long—was originally intended to be 82ft. wide, but in consideration of the increasing size of ocean liners, its width will be 91ft. 10½in.

## THE PRESENT STATUS OF FACE-HARDENED ARMOUR.[*]

The apparent difficulties which at first delayed the development of face-hardened armour in the United States have either disappeared upon closer inspection or been practically overcome. The armour manufacturers have been able to devise methods of controlling, within certain limits, the distortions due to water hardening, and where this distortion occasionally exceeds a practical tolerance, the subsequent rectification has become, with increased experience, more frequently possible without re-tempering. The tolerances of final shape and dimensions have been made slightly greater than in the case of homogeneous plates, to avoid, as much as possible, the stresses of cold rectification or the loss of surface carbon in re-heating. This has necessitated arrangements by which, in certain cases, the lengths of the armour bolts are determined by actual measurement after the plate is in position. The shrinkages and change of angles in the various processes of cementation and tempering, complicated as they were by those of bending and rectification, seemed to follow no definite law; still the manufacturers have succeeded in foreseeing them with sufficient clearness to make most satisfactory butts and joints in the armoured structures thus far inspected.

The difficulty of securing structures to the hard face, in default of knowledge as to the exact location of the fastenings is also in course of solution. It was found feasible to tap and drill holes in the face of the plate at any stage of the process prior to hardening without detracting from the plate's resistance; but, as it was impossible to locate these holes with precision without fitting the armour into place, this method was abandoned in favour of one by which the carbon was prevented from penetrating over certain areas in the wake of the fastenings. This method also had its disadvantages in that the carbon gases frequently seeped through the protecting material and carbonised the surface beneath. The most satisfactory method, and one which will probably be employed in the future, is that of electrically annealing the surface to be drilled.

The greatest objection to the face-hardening or Harvey process, and one which seems least likely to be overcome in the immediate future, is its expense. The thickest plates are exposed to high temperatures for weeks at a time, and the charges for repairs, fuel, and labour are very great. It seems possible, however, that means may yet be determined for shortening this stage of the process and reducing somewhat the temperature required for cementation. The repeated machining, however, can hardly be dispensed with; shrinkage and distortion occur not only in the hardening, but in the cementation as well. Plates must be at least approximately machined before cementation; they must then be shaped and machined to such dimensions as experience has taught will, after hardening, be satisfactory. Even then it may be necessary to anneal, machine, and re-temper, before obtaining satisfactory results. These difficulties of the manufacturer, although reduced by skill and experience to the minimum, are likely to remain permanent.

The following is a table of the Harveyed plates now manufactured for the U. S. Navy:—

*Dimensions and Shapes of Harveyed Armour Plates now Manufactured for the U.S. Navy.*

| Length and width. | Thickness of plate. | Shape of section. | Curvature. | No. of plates now manufactured. |
|---|---|---|---|---|
| 16' 7" × 7' 6" | 18" | Tapered, 18" for 4', then tapered to 8" in 3' 6". | Shaped to side. | 27 |
| 12' × 8' 4" | 17" | Rectangular. | 25°, radius 15' 10" | 52 |
| 19' × 6' 9"·5<br>17' 6" × 6' 9"·5 | 15" | Rectangular. | 66°, radius 14' 3" | 16 |
| 20' × 6' 11" | 12" | Tapered, 12" for 4', then tapered to 7" in 2' 6". | Shaped to side. | 21 |

The decision of the Armour Board of 1890 that the Schneider nickel steel plate was softer than that of steel, and allowed greater penetration, was correct for those two plates. Our armour makers, however, have had no difficulty in making oil-tempered nickel steel armour far stronger and more resisting than that of simple steel, while it still retained the characteristic toughness of the nickel. To any metallurgist acquainted with the infinitude of results that may be obtained by a variation in the composition and treatment of simple steel, the advantageous possibilities arising from the introduction of so benign an ingredient as nickel must be apparent. In other words, where simple steel is strong and tough, both qualities may be improved by adding the proper amount of nickel. The susceptibility of nickel steel to treatment is remarkable, and yet this steel may be abused in the most shameful way without failure. For this reason the smaller percentage of losses in manufacture will go far towards wiping out the increased cost of machining the tougher material. Nickel appears to render the carbon more sensitive to hardening, and hence water-hardened Harvey plates of nickel steel are toughened at depths hardly affected in simple steel plates. Not only that, but the hardening is accomplished with less risk to the plate, and it is for this reason that the manufacturers of the Loire have been able to forego entirely oil-tempering armour plates and obtain the increased resistance due to the more severe operation of water hardening. Doubtless the difficulty of spontaneous hardening, which Mr. Ellis mentions as occurring in carbonised nickel steel plates, is due to the sensitiveness of the alloy after its long heat soaking, the plates being removed from the cementing furnace or uncovered in a cold moist atmosphere while still at a high temperature. It is very rare that any difficulty of this sort occurs in the United States. In fact, the only doubt concerning the use of nickel in this country is the feasibility of raising its percentage—now 3·25 per cent.—still higher, the improvement and cheapening of the processes of reduction having considerably reduced its cost. In this reduction, it is well to note that in the Pola, Austria, competitive armour trial of November, 1893, a Witkowitz unhardened plate, said to contain 5 per cent. of nickel, defeated five competitors, including a Vickers-Harveyed simple steel plate and a Krupp gas-hardened plate. These plates contained between 2 per cent. and 3 per cent. of nickel. Finally, in England, where the nickel in Harveyed armour rarely exceeds 2·5 per cent., its peculiar toughening effect is taken advantage of by employing it for unbacked structures, while the Harveyed all-steel armour, being more susceptible to backing, is now only fitted on backing. There is, therefore, nothing in the present application of the Harvey process, nor its future possibilities, to indicate the disuse of nickel in armour; rather that by increasing its percentage the toughness of the foundation plate and its resistance as a whole may be increased.

The service tests for Harveyed plates for United States naval vessels require them to withstand two shots, the first delivered with the velocity which, according to the Gâvre formula, would cause the perforation of a wrought-iron plate 10 per cent. greater in thickness, together with 36in. of oak backing, the requirements being that no crack shall extend from the impact to the edge, or from one edge to another of the plate, and at the same time through the entire thickness of the plate at an edge. The second shot is at the velocity which, according to the De Marre formula, would cause the perforation of a Creuzot steel plate 15 per cent. greater in thickness, together with 36in. of oak backing, the requirement in this instance being that the projectile, or any fragment thereof, shall not pass entirely through the plate and backing. These tests are but 15 per cent. more severe than those required for oil-tempered nickel steel plates, and are now 3 per cent. less severe than those fixed by the latest contracts in France. It has been claimed that the larger calibres employed in France make the test more severe. This is hardly the case, as in France cracking is not barred. The plate must resist perforation, no part of the backing must be exposed, and the plate must remain in such condition, as regards cracks, as to enable a second shot to be fired upon it. The velocity of the second shot will be 1·26 as compared with that for ordinary steel as obtained from the De Marre formula, and the blow of this shot shall fall at a point distant three to four calibres from the first. Should the plate stop this shot, a premium of 8 per cent. of the contract price will be paid. Should the plate fail to fill the conditions imposed for the first shot, then another shot will be fired with a velocity of 12 per cent. greater than that capable of piercing an equal thickness of steel, and if the plate successfully resists this attack, the lot may be accepted, but at a price reduced 8 per cent. below that agreed to in the contract. It would thus seem that the minimum requirement in France, after all, is hardly as severe as our own; still there are three grades of quality and three prices under the same contract. It must be remembered, however, that the tests in the United States do not, as abroad, fix a standard of excellence. They mark the inferior limit, as does the last shot mentioned in the French contract above. The poorest, not the average, plate in an armour group of from 300 to 500 tons must pass this test or the entire lot is rejected. With the careful inspection of the various delicate operations of manufacture, aided by physical and chemical tests, it has been possible for the inspectors to select a Harveyed plate believed in every instance to be less resisting than any other in the group. Our service plates must, therefore, be regarded as generally exceeding the resistance of the plates tested by a considerable amount. It is to be hoped that an actual comparison of the products of American and foreign armour makers may be arranged at no distant day, if for no other reason than to correct certain false impressions that exist abroad as to the standard of acceptance in this country.

Thus far twenty-eight Harveyed plates, all but seven being of nickel steel, have been tested in the United States, and forty, all of which but fourteen were of nickel steel, having been tested abroad. In addition, nine plates tested were face-hardened in various other ways. The owners of these special processes of face-hardening have, however, in every instance also acquired the right to Harvey armour. In England about 20,000 tons of armour of this description have been ordered, the latest contract being for 12,500 tons, intended for the barbettes and citadels of the first-class battleships Prince George, Hannibal, Victorious, Jupiter, and Mars. Harveyed armour is now being manufactured for the battleships Renown, Majestic, and Magnificent in England, the St. Louis and Charlemagne in France, one Danish vessel, and two Japanese. The great English firms of Cammell, Brown, and Vickers are all provided with Harveying plants. In France the St. Chamond, Chatillon-Commentry, Marrel Frères, and St. Etienne works have adopted the process, the first three accepting contracts to furnish plates up to a thickness of 15·75in., St. Etienne making plates under 8in. in thickness. Schneider and Co. have also acquired the process, as well as the firms of Krupp, Dillingen, and Witkowitz, all of whom had previously employed special face-hardening processes of their own.

There is naturally a wide range in the comparison of the resistance of homogeneous and Harveyed plates, for, even were the plates before treatment made as uniform in composition and quality as the art permits, the accumulated effect of uncontemplated variations in cementation and hardening, especially at different establishments, is sufficiently great to produce a marked difference in their resistance. Equally important are the variations in quality and make of the projectiles. It would be presumptuous, therefore, to state, except in the most general terms, what the resistance of a Harveyed plate is in terms of that of an iron or simple steel plate of equal thickness. Certain French authorities place the resistance of Harveyed plates at about 1·35 that of simple steel, or 1·80 that of iron. English authorities regard the results of the trial of a 6in. Harveyed plate as indicating a superiority, when compared with iron, of 1·83. Another French authority states his belief that good Harveyed plates are able to keep out projectiles whose calibre equals their thickness at velocities of from 1968ft. to 2132ft. American plates compare very favourably with these estimates, Carnegie 6in. plates having kept out 6in. projectiles with velocities up to 2110 foot-seconds, exhibiting a resistance, as compared with iron, of 1 93; while a Bethlehem 8in. plate kept out an 8in. projectile with a velocity of 2004 foot-seconds, showing a resistance 2·14 times that of iron. Nevertheless, the unjust and erroneous comparison is frequently made of the severity of the acceptance tests of armour in this country and the competitive tests abroad. It is difficult to explain some of the errors of an essayist in the journal, *Le Génie Civil*, of August last, who confuses the trials of our homogeneous oil-tempered and Harveyed plates, and calls attention to the low velocity with which the former are attacked in comparison with those employed against face-hardened armour abroad. The American oil-tempered plates classed by him with Harveyed armour are as follows:—The Indiana 13in. B.L.R. turret—actually the Indiana 14in. diagonal armour—manufactured by the Bethlehem Iron Co., and tested May 21st, 1892. The Montereys 12in. B.L.R. turret, manufactured by the Carnegie Steel Co. The Monadnocks 11·5in. barbette plate: This plate in the table is classed as a Bethlehem plate, in the text as manufactured by the Carnegie Steel Co. The latter is correct. The plate contained an extensive defect in its upper end. In discussing the trial of the 18in. side armour plates for the Indiana, the velocity of the first short is given as that merely necessary to perforate 18in. of iron instead of 19·8in. of iron and 36in. of oak backing. There are many other errors unfavourable to American armour in this essay, which are all the more remarkable as the press of this country, invariably well informed, has correctly reported the trials in every instance.

A table for the purpose of reference rather than comparison is appended, giving a synopsis of the tests to which Harveyed armour has been subjected in this country. In one respect this table is less favourable to American armour than those published abroad, as the full thickness of backing employed is considered in calculating the velocities of perforation. Obviously, in the comparison of the behaviour of two target structures, one of which is barely perforated, and the other not even severely taxed, the ratio of the velocity employed to that necessary to perforate a similar target of iron is without meaning or value in the second instance. Only those ratios are available for comparison where the behaviour of targets and projectiles are identical. It will be noticed that the American trials have not had for their object the determination of the ultimate resistance of the plates, except in the case of one or two containing surface cracks, so much as the test and development of Harvey armour-piercing projectiles.

The above remarks are intended to refer to the practical and commercial status of face-hardened armour with regard to the service, rather than its experimental and speculative condition. Necessarily the latter is considerably in advance of the former in so new and complicated a process, especially as the only means of gauging the advances made are involved with the comparative quality of projectiles, themselves in course of development. Harveyed armour has been attacked both in this country and abroad by projectiles fitted with soft steel caps on the plan first devised by Colonel Inglis, of the English Ordnance Committee, in 1883, for trial against compound armour. The theory of these caps is twofold. First, upon impact they are penetrated by the shell point and swaged back along the bourrelet, jacketing and supporting it against rupture until it enters the plate and is supported by the walls of the shot hole. There does not seem much advantage in this procedure, as the point of rupture of the projectile is usually quite near the bourrelet; and the cap would have become too much attenuated and weakened, before slipping back to that point, to offer much assistance. There is, in fact, reason to believe that the cap does not act in this manner at all, as in no instance has it been possible to discover a trace of it before the plate, where it would probably have remained had it merely served as a support to the projectile. The second and most plausible explanation of the benefit ascribed to the cap is that it acts as a lubricant or sleeve which is carried into the plate surrounded by the jagged fragments of hardened surface. These pieces, incapable of flowing, surround the head of the projectile, scoring and abrading it while preventing the forward flow or displacement of the metal, thus bottling up and bracing the resistance of the plate against the advancing projectile. It is evident that if any part of the cap can be carried into the face of the plate with the projectile, the resistance of this non-viscous material is felt over only a part of the ogival instead of the whole of it. There is strong reason to believe that in the latest tests made in this country with capped shell the quality of the projectile had more to do with its success than the presence of the cap, as in two instances the point of the projectile was either broken off or smashed in. In all cases, however, the action of the hard, inextensible face surrounding the head of the entering projectile is plainly shown in the spiral scores and grooves cut on the ogival of a shot which has perforated a Harveyed plate. When, therefore, we are shown the photographs of French and Russian shells which have either perforated, or rebounded after penetrating, a Harveyed plate, without exhibiting a sign of a scratch, we are compelled to state in the light of past experience that the plate was not a good type plate, being too soft, and tough rather than hard.

It was but recently that foreign compliments were showered upon our projectile makers, who were declared to lead the world in certain respects. It may be most positively asserted that there is no reason to believe they have suddenly lost that position. The advent of Harveyed armour, and the necessity of our Navy being provided with projectiles capable of piercing it, if such projectiles could be made, were almost simultaneous. The standard of excellence to be struggled for was far in advance of what was, until very recently, regarded as attainable. The improvement in quality, however, has been remarkable. Two months ago our Harveyed armour, as mounted on the ships, was regarded as impenetrable to calibres equalling its thickness up to 8in., the impact occurring with service muzzle velocity. This was owing to the smashing of the projectile on the hardened face. Projectiles of the latest design, however, would probably be able to perforate such plates practically undeformed at a fighting range of 1500 yards. It has been reported that the Russians so easily overcame Harveyed armour with their special shells that they decided against it in favour of tempered homogeneous plates. They are yet to be heard from in this matter, however, and it is hardly possible that they have followed a policy which, if generally adopted at any time in the history of armour, would have effectually stopped progress. Neither in the arts of the gun-maker nor those of the shipbuilder have the application of improvements been deferred until they appeared fully perfected and final in character. It is only by keeping close up with the advance line that full advantage may be taken of new developments in arts and processes, or the scientific discoveries daily taking place around us.

The theory has been advanced, however, that with the improvement of projectiles—not necessarily capped, as that feature can hardly be regarded as practicable and serviceable—the Harveyed plate will lose its peculiar advantage now due to its smashing the projectile, and will become really less resisting than a homogeneous plate of equal thickness, on

---

[*] Abstract of a paper by Captain W. T. Sampson, United States Navy (Chief of the Bureau of Ordnance), read at the annual meeting of the American Society of Naval Architects and Naval Engineers, held in New York, November 15th and 16th, 1894.

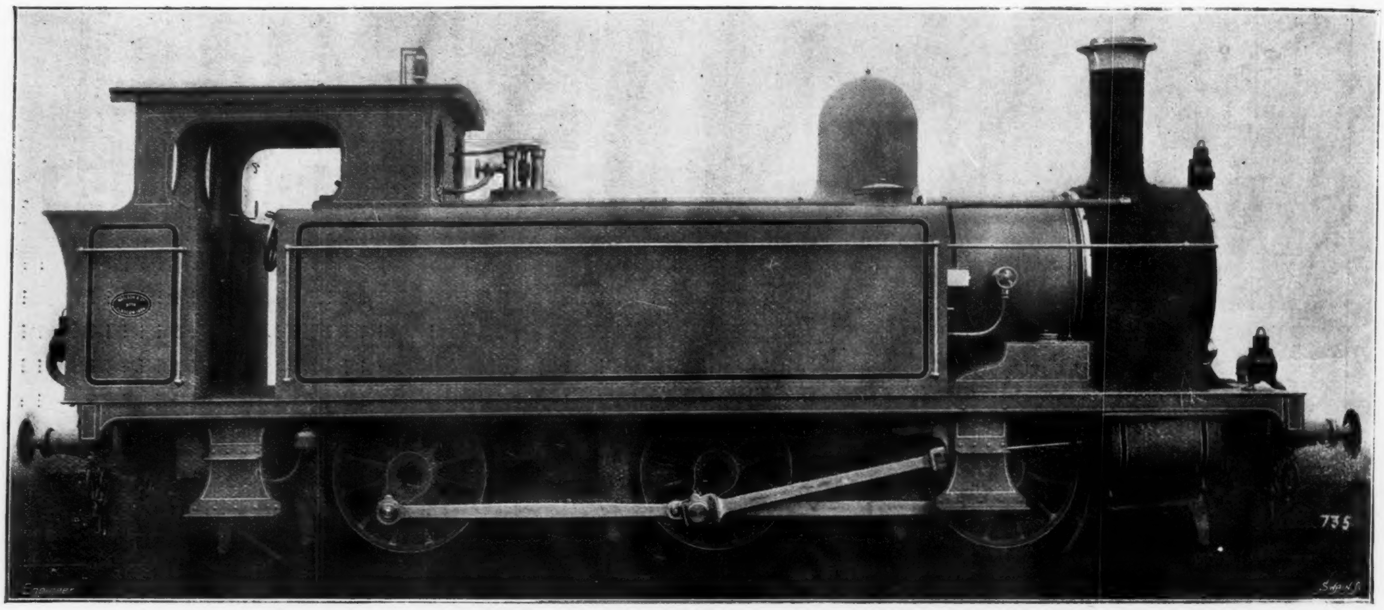
## TANK LOCOMOTIVF, NIPPON RAILWAY, JAPAN

MESSRS. NEILSON AND CO., GLASGOW, ENGINEERS



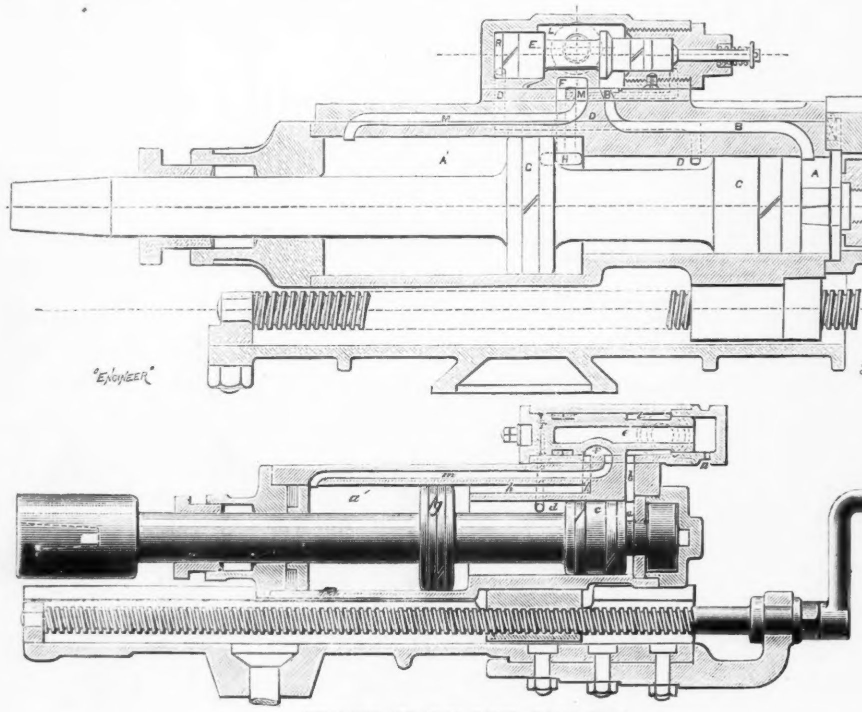
account of the softer body and back of the Harveyed plate. This argument is fallacious; the principle of a non-homogeneous hardened face, combined with a decrementally toughened body and back, is correct. The homogeneous plate, as compared with the non-homogeneous, must always be perforated in detail. Should the homogeneous plate of the future be greatly superior to the face-hardened plate of to-day, it will be made still more resisting by employing it as the foundation plate to which the process of face-hardening is applied.

Whatever conclusion is reached, the fact remains that Harveying in its present state has increased the resistance of armour fully 35 per cent., and perhaps 50 per cent., according to the thickness of the plate. It has also brought about a great improvement in the quality of our projectiles, and in doing so has perhaps lost some of the advantage it held over them at first when subjected to direct impact. Its superiority under inclined impact is nearly as great as it ever was, and it does not seem possible that in this respect the relation between gun and armour will, for a long time to come, take the old position held in the time of soft armour. Perhaps this relation may be restored, however, should the thickness of armour be reduced to a point allowing no more than the old resistance, in order to distribute it over a larger area or divert the weight thus saved to other uses.

## QUICK LOCOMOTIVE BUILDING.

Messrs. Neilson and Co., Hyde Park Locomotive Works, Glasgow, have succeeded in establishing what may be considered a record in locomotive engine building. On the 26th of September they received an order for twelve locomotives for the Nippon Railway Company of Japan, the penalty for late delivery being exceptionally severe, viz., £100 per week per engine for each and every week by which the contract dates might be exceeded. The delivery promised by the firm for the first four engines was the 15th of January, 1895; the second four engines by the 29th of January, 1895; and the third four by the 12th of February, 1895. The photograph which we reproduce above of the first engine was taken on the 30th of November, 1894, or just sixty-five days after the reception of the order. The first four engines were passed, after trial in steam on the railway in working order, on the 5th of December, 1894, or in seventy days from the receipt of the order. The fifth to the eighth engines were completed and tested on the 12th of December, 1894, or in seventy-seven days from the order; and the last four engines were passed in steam on the 19th of December, 1894, or in eighty-four days from the receipt of the order. The first four engines were despatched for shipment on the 15th of December, 1894; and it is expected that the whole order may be *en route* for Japan this year, or well within the time undertaken for delivery of the first engine.

Messrs. Neilson and Co. acknowledge that they would have been quite unable to accomplish the above result but for the strenuous exertions of their efficient staff and the co-operation of their own workmen, to whom the result is most creditable. Further, in the matter of inspection the contractors were greatly assisted by the consideration of the consulting engineer, Mr. T. R. Shervinton, and his staff of inspectors, who made it a personal matter to accelerate the inspection of the material of the engines, placed as it was with sub-contractors whose works are situated all over England and Scotland, and this notwithstanding that the inspection was as exacting as necessary to insure that nothing but material of the best quality should be built into the engines. As Messrs. Neilson and Co. had not built the same type of engine previously, new drawings, patterns, and templates had to be made, and the material ordered, inspected, and passed before a start could be made in the works. We believe that this is not only a record for Messrs. Neilson and Co., but also among locomotive builders; but it is almost certain that with other conditions prevailing, such as order books well filled up and sub-contractors busy, such a severe penalty as £100 per week per engine for late delivery could not be accepted under any consideration.

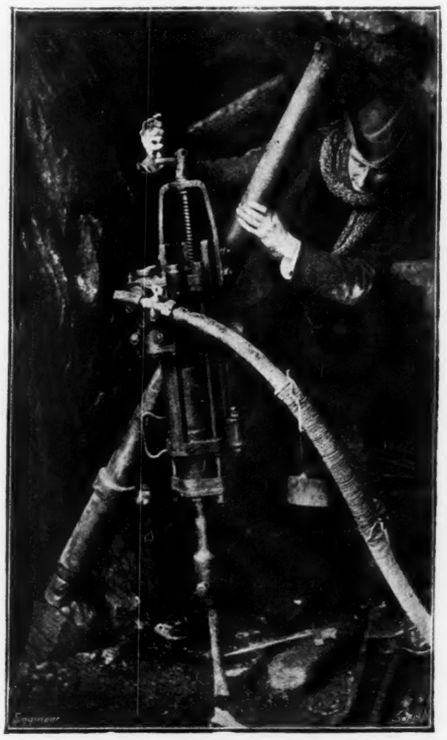


SECTIONS OF THE RAPID ROCK DRILL

## A RAPID ROCK DRILL.

We have recently been enabled to see at work an ingenious rock drill. The principle of this drill is not absolutely new—in fact, its invention dates about two years back, but since that time sundry alterations have been made which have gradually brought the working of the drill to its present state of efficiency.

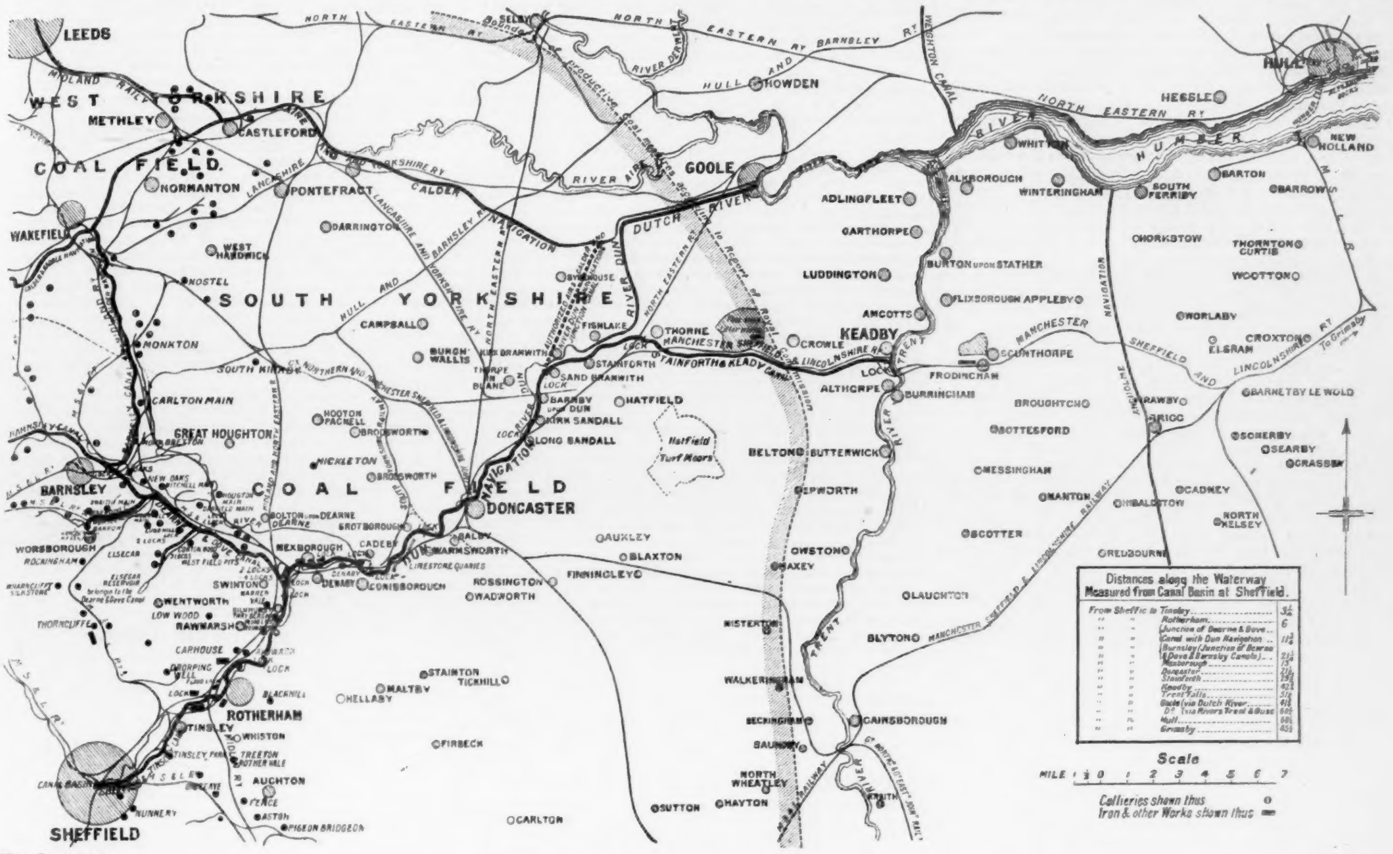
The compound action, which is the leading feature of the drill, was originally invented by Mr. P. J. Ogle, who sold his patent rights to R. Schram and Co. in consequence of the immediate recognition of its value bestowed by that firm on the invention, which recognition led to adoption, even at the cost of many pangs occasioned by the shelving of their old drill, which had already rendered and continued to render excellent services. This was only done reluctantly, but the old drill had had its day, and was obliged to give place. We are inclined to share Mr. Schram's opinion that the preference has been amply justified, and expect that the figures given lower down will convince our readers in a similar manner.



THE RAPID ROCK DRILL AT WORK

But we should at first explain the mechanism, a glance at the accompanying sections of which will be sufficient to show the main feature, namely, the two pistons of unequal sizes. The advantage of this over the simple method is plain to see—as the air that has been used to make the forward stroke, instead of being exhausted to the atmosphere, by being taken to the underside of the lower piston, is utilised for the backward stroke, a more powerful and rapid stroke being the inevitable result, in addition to a saving of compressed air consumption, according to Mr. Schram, of 40 per cent. The sections A and B are of two types of the drill—there being no difference in the principle between the two; B represents the more recent form.

# THE CANALS OF THE SHEFFIELD AND SOUTH YORKSHIRE NAVIGATION



"THE ENGINEER"

The operation is as follows:—Assuming the piston valve *c* to be in the position shown, the cylinder *a* will be in communication with the air under pressure through the port *b*, the cylinder *a'* being at the same time in communication with the atmosphere through the ports *m*, *f*, *h*, the result of which combination will be that the piston is forced forward, and, in its travel, uncovers the port *d d d*. Through this port some of the compressed air passes into the small cylinder *r* behind the valve, and acting on a larger area than that which is subject to the constant pressure at *l*, there being no resistance, as the other end communicates with the atmosphere, pushes the valve over, cutting off the air supply and placing the cylinders *a* and *a'* in communication through the ports *b* and *m*. Then the air that has acted on the piston *c* now passes into the cylinder *a'*, where it acts on the larger piston, thereby moving it back to its original position, the piston *c* at the same time uncovering the port *d* and placing the cylinder *r* again in communication with the atmosphere through the ports *d* and *h*, the constant pressure acting on the valve at *l* moving it over to the position as shown in the illustration, and thus the action is repeated.

It will be seen that the air used for the forward stroke is again utilised for the backward stroke without in any way impeding the piston in its forward stroke, and by being instantaneously admitted to the cylinder *a* while the cylinder *a'* is in free communication with the outlet, causes the piston to give a very powerful blow. At the end of each backward stroke there is still some pressure left behind the piston C, which, besides cushioning the piston, causes the space in the cylinder to be more quickly filled, thus causing a saving in air in addition to the increased power of blow. Briefly, what we saw was as follows:—

An "Optimus" drill was tested against one of the old Schram drills: firstly, with regard to depth of hole within a given time—namely, one minute—the rock being a block of Cornish granite; and secondly, with regard to air consumption. In the depth test, which lasted one minute, with 70 lb. air pressure, the Schram drill cut a hole 9¾in. deep. In the same time the Optimus cut a hole 11⅜in. deep. In the consumption test, which also lasted a minute, both drill stocks delivering blows on a log of wood at the end of the stroke, the Schram drill, with air pressure, maintained throughout at 60 lb., took 175 charges of the air compressor, the cylinder of which is 8in. diameter by 12in. stroke; the same air pressure could not be maintained with the Optimus drill, as this drill, requiring only 90 charges of the compressor, took the air so slowly that the combined engine and compressor on wheels when even working at 58 lb. betokened a strong dislike to its surroundings—by a visible and audible tendency to leave them. The dancing of this machine could only be stopped by working the drill at 56 lb. pressure. When the air supply to the Optimus was cut off—the drill continued to work—without the tool, be it rememberd—until the air pressure by the gauge fell to 17½ lb., thereby furnishing another proof of the much reduced amount of air required. Comparing the weights of the two drills, we find the Optimus somewhat in excess, weighing 295 lb., or 75 lb. more than the Schram. In considering this, the additional length of stroke of about 1in. should be borne in mind. The drills were tried at the works of Messrs. J. I. Thornycroft and Co., where they are manufactured for Richard Schram and Co., 17A, Great George-street, S.W.

---

## SHEFFIELD AND SOUTH YORKSHIRE NAVIGATION COMPANY.

In 1889 an Act of Parliament was obtained enabling a new company to be formed in Sheffield, with powers to acquire by compulsion the waterways between Sheffield and the Trent, as well as the Dearne and Dove Canal, which connects the main line of navigation with Barnsley and the intervening coal-field, all of which belong to the Manchester, Sheffield, and Lincolnshire Railway Company. These powers have not yet been put in force; but in the beginning of this year an agreement was arrived at by which the railway company agreed to sell to the canal company the navigations in question for the sum of £600,000 cash, and £510,000 fully paid-up ordinary shares in the new company. An arrangement was also completed defining the land which should attach to the railway and that which should remain the property of the canal, where both lines of communication are contiguous; thus dispensing with the necessity of calling in the Railway and Canal Commissioners, the tribunal prescribed by the Act of Parliament in case the parties were unable to come to any understanding between themselves. The new company has lately issued a prospectus, and as it is supported by the leading men of Sheffield and neighbourhood, who have subscribed £270,000 of the preference shares out of the £625,000 which it is proposed to raise, we hope that the balance will be obtained without any difficulty, and that an important line of water communication will be henceforward freed from railway control. The Navigation Company intends to raise money for certain improvements of the waterway by the issue of debentures hereafter.

We publish a map showing the district served by the waterways which it is intended to purchase from the Manchester, Sheffield, and Lincolnshire Railway Company, extending from the towns of Sheffield and Barnsley to the tidal waters of the Trent at Keadby. The length of these waterways, in parts canal and the remainder formed by the canalisation of the river Don, is from Sheffield to Keadby forty-five miles, with a branch to Barnsley nine miles, and subsidiary branches to Worsborough and Elsecar each two miles long, making a total of nearly sixty miles. These form a water communication between Sheffield, Rotherham, and Mexborough, and this portion of the Don Valley, which is inhabited by a large and industrious population numbering 600,000, as well as Barnsley and the South Yorkshire coal-fields, with Hull and the outside world. The traffic on the waterway is, however, comparatively small, about 500,000 tons passing to and from the Trent at Keadby, and another 400,000 tons being carried from place to place on the system. This compares with upwards of 2,000,000 tons carried on the neighbouring Aire and Calder, and upwards of 2,000,000 tons on the Bridgewater Canal, which has a much smaller sectional area, and is not navigated by barges that can be sailed in the estuary of the Mersey. All barges navigating the Bridgewater Canal are tugged by the canal company's steamboats if bound for Liverpool, whereas the barges locally known as keels on the Sheffield Navigation make their passages by sail, not merely to Hull and other ports on the estuary on the Humber, but also to the harbours and navigations of Lincolnshire and the adjoining coast.

The history of these navigations is a peculiar one. The first Act of Parliament goes back to 1726, five years after the Acts for making the Weaver, and Mersey, and Irwell navigable; twenty-seven years later than the Act for the Aire and Calder Navigation. The Act was granted to the Cutler's Company of Sheffield, with power to make the river Don navigable from Tinsley, two miles below Sheffield, to Doncaster—a small beginning indeed. In the following year the corporation of Doncaster obtained an Act to extend the navigation to Wilsick, six miles lower down the river; and the two undertakings having meanwhile amalgamated, obtained an Act in 1740 to extend their operations four miles, as far as Fishlake. As a spring tide flows to within four miles of Doncaster, the navigation overlapped the tide. No lock appears to have been built below Doncaster, so that the boats could only pass over this portion at high water of spring tides, and delivered their cargoes two miles away from Sheffield. This state of things appears to have lasted for fifty years till 1793, when Acts were obtained for making the Dearne and Dove Canal to the Barnsley coal-fields, and also for making a canal from the Don at Stainforth to the Trent at Keadby, which afforded a passage for barges at neap as well as at spring tides; and after these were completed an Act was obtained in 1815 to extend the waterway from Tinsley into Sheffield, and under the powers then conferred the canal, four miles in length, with twelve locks and a canal basin of 1½ acres in extent, was made, and Sheffield brought into contact with the sea for craft carrying fifty tons.

The difference in level between the Trent at high water and Sheffield Basin is 160ft., and the locks number thirty-one. Certain improvements were made from time to time below Tinsley, so that the burthen of vessels could be increased to 70 tons or 80 tons, and sailing craft with lowering masts were able to trade to Sheffield. The limit of draught, 6ft., is fixed by the depth of the Sheffield and Tinsley Canal. About 1847 the owners of the Dun Navigation, alarmed by competition of railways, became themselves the makers of a railway alongside a portion of their waterway, and obtained leave to make the South Yorkshire, Doncaster, and Goole line, and from that time the railway interest overshadowed the interest in the waterway. The company subsequently became possessors of the Dearne and Dove Navigation, and also of the Stainforth and Keadby Canal, and a few years later offered to place the whole of their property in the hands of the Great Northern Railway Company. This proposal fell through. Meanwhile, the Manchester, Sheffield, and Lincolnshire Railway Company purchased the Sheffield and Tinsley Canal, and having thus secured the terminus, they, in 1864, made arrangements for the lease for 999 years of the whole undertaking, including railways and navigations belonging to the South Yorkshire and River Dun Navigation Company. Ten years ago the latter company was dissolved and merged absolutely in the Manchester, Sheffield, and Lincolnshire Railway Company.

Up to 1847 the navigations were in a fair condition compared with others throughout the country; indeed, the lower portion from Keadby to Doncaster was, perhaps with the exception of the Gloucester and Berkeley Canal, the finest inland navigation in England; fixed bridges had been replaced by swing bridges, and vessels with fixed masts, drawing 8ft. of water, could trade to Doncaster; but after 1847, and especially since the lease of 1864, the railway has pressed sorely upon the navigation. Fixed railway bridges have been built by the company below Doncaster leaving no more than 12ft., while above bridges have been built with even less headway. Ugly bends have been made in the canal to pass it under railway bridges, and in at least one instance the canal has been filled up and a line of rails laid on its site, the waterway being elbowed out of its normal course, and the alternative route provided being much less convenient for the traffic by water.

Verily the mistakes made by former generations are being brought home to the men of to-day, who find that legislation has permitted the throttling of the old navigations, and their transfer to competing railway companies. Upwards of one-third the mileage still open to navigation in England is now in the hands of railway companies, whereas on the Continent the rule is for the State to own the waterways. In France, at any rate, the majority of them are toll free, intensifying the competition our traders have to contend with. The Mersey and Irwell might have been secured to the city of Manchester, but failing that it was held by independent canal owners, the trustees of the late Duke of Bridgewater, and it was due to their watchfulness and authority that swing bridge clauses were inserted in all the Acts of Parliament empowering lines of railway to cross the Mersey. This provision aided materially the promoters of the Manchester Ship Canal in obtaining the necessary power to raise the railways to a sufficient height to enable ships to pass under them. It was impossible to enforce the swing bridge clause on the face of the heavy traffic carried on these lines, and the canal company has been compelled to spend an enormous sum in raising the four lines of railway that crossed the Mersey Valley at a low level to the height of Runcorn Bridge, 75ft. above the canal, and, in addition, to compensate the railway companies for alterations entailed in the conduct of their traffic to the extent of over £100,000.

Sheffield and Doncaster, as we have seen, once owned the navigation, and had they retained possession of it would certainly have seen its interests better protected, and by free competition would have saved the district untold sums paid to the railway company for carriage. The neighbouring Ouse navigation, owned by the Corporation of York, is crossed by swing bridges, and the headway is preserved to the older line of traffic. The existing locks on the Sheffield navigation will accommodate a vessel 62ft. by 16ft., the depth to Sheffield being limited to 6ft. by the Tinsley Canal, below this there is a minimum of 6ft. 10in. on the shallowest lock sill; there are shoals and other obstructions which require removing on various parts of the navigation.

The result is that 80 tons to 90 tons is considered a fair cargo to carry to Sheffield, although the same craft will take 10 tons more by the Aire and Calder to Leeds, and as the charge made is at per ton, the difference of earning in the trip is 11 to 12 per cent. But of much more importance to the trade of the district, as well as to the boat owners, who fix the freight according to the earning power of their craft over a period of time, is the fact that owing to the want of accommodation at Sheffield and Keadby, and generally to the lethargic fashion in which the whole navigation and its surroundings have been worked, delays are the rule; and although the trip to Hull ought to be accomplished at need in about thirty hours, the time occupied varies from four days to three weeks, and a trip a month, or twelve trips annually, is considered fair work for a keel, as is a trip a week to a colliery only ten miles distant. Even Ireland beats this, for on the Grand Canal boats make trips from Dublin to Limerick and back, 94 miles, and discharge and load cargoes each week.

The Sheffield basin is still 1½ acres, as made in 1815, when the population was about 60,000. All the accommodation provided for the additional 260,000 inhabitants is to be found at the various goods depôts of several railway companies. The warehouses are unaltered; we were going to say the cranes were, but a fourth crane has of late years been added to the three small ones previously provided. None of these are worked by power, although the basin is usually so crowded with barges that they are kept waiting below Tinsley; and to accommodate the heavy trades of Sheffield, including armour-plates, guns, boilers, &c., a 5-ton crane is the maximum limit which the Manchester, Sheffield, and Lincolnshire Railway Company consider the carriers by water are entitled to. There is but one berth in which a vessel can unload perishable goods under cover—consequently rain stops the work on all the others loading or discharging such goods; and although the traffic is congested to a degree, the basin is closed regularly at 6 p.m. even in the long summer evenings.

The valley is, as we have stated, a populous one; its manufactures are mainly what are known as heavy, and there is abundance of coal—land-locked coal, as one of the witnesses who gave evidence in favour of the Bill termed it. Foreign ores are imported largely, including Swedish iron; and these have to be exported in a manufactured state. Two payments for carriage have therefore to be considered.

The railway rate for South Yorkshire coal to London, exclusive of truck hire, is about 8s. per ton, and it is calculated that with the improved navigation the cost will be considerably reduced, thus enabling the excellent gas coal raised in the neighbourhood to be brought into competition with the South Durham coal for supplying the Metropolitan and South Country Gas Companies. Messrs. Cory and Co. are building a number of barges to carry 200 tons to 300 tons dead weight. These can navigate for a long length on the Aire and Calder, and also to Keadby. It is proposed to alter this navigation so that they can be loaded at the Denaby Colliery Company's stages. This company has an output of 1,000,000 tons per annum, and has lately sunk a new pit on the banks of the Dun.

It appears from the evidence given before the Parliamentary Committee in 1889 that there is no scarcity of water on this navigation. The river Dun supplies the main line from Sheffield to Keadby, and as will be seen by reference to the map, there are large reservoirs on the Dearne and Dove Canal. The waterway is not so deep as the Aire and Calder is now, but we see no reason why it should not be improved in a similar manner. It would appear as if the promoters had contemplated doing this, for they, in conjunction with the Aire and Calder, have obtained power to make a canal, as shown by dotted lines connecting the Aire and Calder with the river Dun. This would shorten the distance between the colliery districts above Doncaster and the deep water of the Ouse by ten miles, and place the docks at Goole at the service of the Sheffield Navigation. Vessels drawing 15ft. and 16ft. of water can trade to these docks, the channel of the Ouse having recently been improved by training.

Large collieries have lately been opened out in the Dun Valley, and we have lately been told that the centre of the South Yorkshire coal-field will gravitate towards Doncaster, and ultimately be located there instead of at Barnsley. We think, therefore, there is every prospect of a large increase of trade being obtained for the navigation, if managed on modern principles and with modern appliances.

## LETTERS TO THE EDITOR.

(*We do not hold ourselves responsible for the opinions of our correspondents.*)

### LABOUR AND LUXURIES.

Sir,—I do not think that any good could be done by continuing this discussion so far as I am concerned; but before definitely withdrawing and leaving the field to others, I would like with your permission to summarise my statements, the gist and essence of which your correspondents seem to have entirely failed to understand. At the outset I referred to a certain grumble to the effect that a Government clerk spent more than the week's wages of a labourer on a bouquet, and I said that so far as the working population was concerned it made no difference on what the gold was spent. Thereupon your correspondent "W. A. S. B." and others joined issue, and began to argue on ethical grounds that I was wrong. I disclaimed all reference to ethics, and took the position taken by Lord Farrer. Turning back to commercial considerations, your correspondents next proceeded to argue that it was of very great importance to a country on what gold was spent.

Now in one sense this is quite true, and in that sense I have never traversed the proposition. What I did say and repeat is that so far as a working man—and by a working man I mean anyone, judge, physician, director, gardener, porter, or scavenger—is concerned it matters not a jot what kind of work he does so long as he receives gold for it, and I said that the benefit which the possession of gold can confer is quite independent of what has been given in return for it. To go over old ground once more, I say that the benefit which a sovereign can confer on a gardener in return for a bouquet is as great as the benefit which a sovereign can confer on a labourer who is employed in helping to make rifle cartridges. This seems to me to be absolutely incontrovertible on any commercial grounds. Ethically no doubt it is better to grow flowers than to make cartridges, but with this I have nothing to do.

In the next place, I have tried to show that the supply of gold being limited, if one individual obtains it another must go without. That, in a word, both the cartridge maker and the gardener cannot have the sovereign. Thereupon your readers argue that it is a matter of the most serious import to the nation that the sovereign should be properly spent; to which I reply that for various reasons it is of practically no importance at all save in one respect on what it is spent, so long as it is not spent on something that sends it out of the country, and this simply because the spending of gold is not a single operation. It is continually going on. Thus, it may be said, for example, that a sovereign spent on fireworks is wasted. That may be quite true in the sense that the individual buying the fireworks and letting them off does not get value for his money, but so far as the gold is concerned, it passing to the firework maker at once confers on him the power of buying bread for his family, and the gold will do him all the good that it can do if he spends it aright, although it has been earned by making fireworks. In one word, each sovereign during its life is engaged in a multitude of transactions, and so far as a nation is concerned, it can do no more than enable the man who earns it to buy food and clothes and the necessaries or luxuries of life, and no matter how it is earned it will do that. I cannot find a single proof in any of your correspondents' letters that I am wrong. Indeed, they never attempt, so far as I can see, to traverse the proposition at all.

But they do say that a sovereign may be spent to greater advantage in one way than another, commercially. Now I maintain the following proposition:—*Gold is best spent when the spending gives employment to the largest number of workers at fair wages.* Thus, for example, one man spends £50,000 on a great building; that building never decays, never gives employment subsequently to anyone, and is quite unsaleable, but by a mistaken notion it is regarded as so much national wealth. Another man spends £50,000 on a ship; that ship not only gives employment on her construction to a great number of workers, but subsequently she employs a crew and she uses coal, and has to be kept in repair, and finally wears out and has to be replaced. The spending of the money on the ship is infinitely more to the advantage of the nation than the spending of it on a great public building. The point turns on the meaning of the word "advantage." Let me take beer for instance. A man may spend a sovereign which he has earned, either on beer or on mutton. The first use would, I suppose, be regarded as a waste of the sovereign. The second use would be considered, I suppose, an advantageous use of the coin. If we come to sift the proposition thus stated, we see how extremely narrow it is. The advantage and disadvantage are wholly confined to the individual buying the beer or the mutton. But if we extend our range of observation, it will be found that the man spending the sovereign on beer is directing it into a far more useful channel than the man spending it on mutton, because the production of a sovereign's worth of beer gives employment to many more men than does the production of a sovereign's worth of mutton. In New South Wales there is a population of but 1,200,000 souls, yet there are, it is estimated, 60,000,000 of sheep and 2,000,000 of cattle. It is not remarkable that this enormous country is thinly populated, because there is little or no field for labour. No doubt "W. A. S. B." would say better so than growing barley and making beer. But on this point I certainly cannot agree with him.

There is a story told of a dozen men who sat at a table playing cards. After a time the meeting broke up, and accounts were squared; a single sovereign paid everything, and yet each man of the twelve owed a sovereign. Here we have an excellent instance of what gold can do. My contention is that so long as gold is kept, let me say, in England, it matters nothing whether it is spent on necessaries or luxuries, the exact measure of its utility will be the number of times it changes hands. If my antagonists are prepared to show that in the production of any given commodity the circulation of the sovereign is less than it would be in the production of some other commodity, then I am prepared to admit that in so far the gold is not used to the best advantage.

In any great commercial country such as this is, production of every kind is mixed up in a way that the older writers on political economy never dreamed of. Thus, for example, a man spends five sovereigns on a watch; that money is probably distributed among a hundred persons. Such is the division of labour that the man who makes watch cases will not make the hinges for them, which represent a totally different branch of trade. It is the most difficult thing in the world to misuse a sovereign, save in the sense of locking it up or taking it out of circulation.

But someone will say, why not spend the sovereign in paying for useful labour? Why not make more railways, for example? Will not this be better than spending it on flowers? The answer depends on whether it is better for the community as a whole to employ navvies or gardeners. So far as the gold is concerned, one is as good as the other; but it is conceivable that a condition might spring up in which employment being given to no one in the production of corn let us say, that gold had to be sent out of the country to buy it. This would be very bad policy indeed, and I think it will be seen that throughout the correspondence I have positively asserted that gold must be retained in a country, and I now repeat for the last time, that so long as it is retained it will do all the good it can do, no matter on what it is spent, the only measure of its utility being the rate at which it changes hands. As to the utility of what is given in exchange for it that is quite another affair, concerning which I have expressed no opinions of any kind. It is to be regretted that "W. A. S. B." did not quote from Mahan, instead of merely referring to him. Quoting from a writer of the period, Mahan gives the following most instructive passage:—"The mines of Brazil were the ruin of Portugal, as those of Mexico and Peru had been of Spain; all manufactures fell into insane contempt; ere long the English supplied the Portuguese not only with clothes, but with all merchandise, all commodities, even to salt fish and grain. After their gold, the Portuguese abandoned their very soil. The vineyards of Oporto were finally bought by the English with Brazilian gold, which had only passed through Portugal to be spread throughout England." "We are assured," says Mahan, "that in fifty years 500 millions of dollars were extracted from the mines of Brazil, and at the end of the time Portugal had not 25 millions in specie." We have precisely analogous cases in the present day. The discovery of gold in Australia, New Zealand, California, leads at once to the abandonment of agriculture, manufacturing, the sea. The mistake made by the Spaniards and Portuguese was that they sent their gold out of the country. Will "W. A. S. B." venture to say that they would not have been enormously better off if they had kept it? But they did not keep it, for reasons which "W. A. S. B." will find set forth in the pages of Buckle, if only he understands how to profit by the lesson which Buckle has taught.

As I have said, I do not intend to take any further part in this discussion. Indeed, I fear that I have repeated myself many times as it is, but I shall read with interest what your other correspondents may have to say on the subject. Mr. Allan Steward, I see, has raised a very nice question indeed. His views and mine are in the main so far identical. Y. X.

December 22nd.

### AMERICAN AND ENGLISH WOOD-WORKING MACHINERY.

Sir,—A few days ago I came across a letter in a recent issue of your journal under the presumptuous headlines of "Why American Wood-Working Machinery is Damaging English Manufacturing Interests." The said epistle dates from Cincinnati, Ohio, U.S.A., and is over the initials "J. T. B.," who must be exceedingly sensitive not to give us the benefit of his full name. Now, I should like to know what ground there is for such an extraordinary interrogation. Have the English at any time acknowledged such premises? I say decidedly not; on the contrary, the introduction of American machines here has only by comparison served to stimulate the demand for home-made.

While admitting the ingenuity of American machines generally, and the persistency of the makers in pushing their sale, I find from experience that as a rule they are unsuitable for our markets. They are in most cases too lightly constructed, and not fitted in the substantial manner English users insist on.

It is all very well as an excuse for these deficiencies to maintain that American iron, being much tougher than ours, less of it is requisite for the necessary strength and stability; this contention will not hold water. Formerly, when our cousins across the sea made the framing of their machines of wood, it was claimed as preferable to metal, inasmuch as it absorbed the vibrations of the machines arising from the high speeds of the various cutter heads. At present their justification of this lightness is the abnormal toughness of their iron. As a matter of fact, machines of this type and special design, running at exceedingly high velocities, must have framework of comparatively solid construction to counterbalance the effects of vibration. Light framing—irrespective of the toughness or strength of the material composing it—will not suffice to prevent this. Weight, dead weight, is a *sine quâ non*. To affirm that American machinery is rapidly edging the home-made out of the field is hyperbole, and very far from the real position of affairs.

Several transatlantic manufacturers have from time to time established show-rooms in this country for the display and sale of these "veritable wonders," but invariably with disastrous financial consequences. If these machines are so superior to ours why do not our people purchase them? They are, machine for machine, less expensive, so this cannot be the explanation; there must be something deeper to account for it. Most assuredly, the Englishman is *not* behind the times in the getting-up of up-to-date wood-working machinery. The pretentious Cincinnatian in this connection is illusive and fallacious, and doubtless my native contemporaries will unhesitatingly endorse my estimation of his assertions to the contrary. W. Samuel Worssam, Engineer.

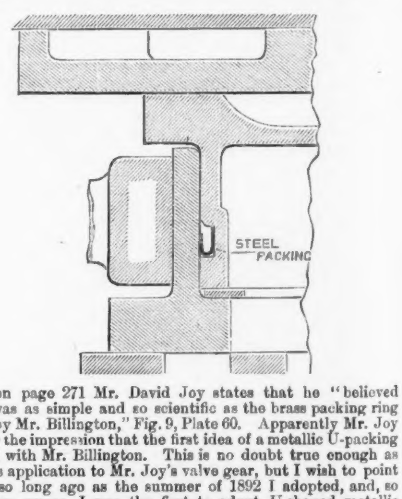
December 22nd.

### METALLIC CUP PACKING.

Sir,—Living as I do in Japan, it is only a few days ago that I received the April number of the "Proceedings" of the Institute of Mechanical Engineers, containing among other things a very interesting paper and discussion on Mr. David Joy's fluid pressure reversing gear. As that discussion, so far as the Institute is concerned, is closed, I shall be much obliged if you will allow a little space in your columns upon one point which appears to have attracted some attention during the discussion. On page 258 of the "Proceedings" of the Institute of Mechanical Engineers Mr. David Joy mentions various kinds of packing which had been tested, including a simple ring of metals of U-section—Fig. 9, Plate 60—which had been suggested by Mr. Billington. On page 268 Mr. Basil H. Joy again alludes to the "simple form of packing suggested by Mr. Billington, consisting of a brass ring of U-section made with a very fine edge, which pressed against the ram, and was held up tight against it by the fluid pressure. It could be made absolutely tight, but it was so delicate that as soon as it was taken out for repairs the fine edge, which had to be practically like a razor, was difficult to preserve, and of course as soon as ever there was a little burr on the edge the whole efficiency was done away with."



Again on page 271 Mr. David Joy states that he "believed nothing was as simple and so scientific as the brass packing ring designed by Mr. Billington," Fig. 9, Plate 60. Apparently Mr. Joy was under the impression that the first idea of a metallic U-packing originated with Mr. Billington. This is no doubt true enough as regards its application to Mr. Joy's valve gear, but I wish to point out that so long ago as the summer of 1892 I adopted, and, so far as I am aware, I was the first to adopt, U-shaped metallic packing for my patent balanced slide valve, which was described and illustrated in the "Minutes" of the Institution of Civil Engineers, vol. cxvii., page 302. Although the illustration is only to a small scale, the U-packing can be clearly made out. My packing, however, is made of steel, as shown in the annexed full-size tracing.

In the autumn of the same year—1892—I sent a working tracing—full-size—and a sectional model—half-size—of my balanced valve to Mr. John Waddington, of 35, King William-street, E.C., by whom they were shown to Mr. Billington, I believe, in 1893, and this probably gave him the idea which, in a modified form to suit the circumstances of the case, he afterwards suggested to Mr. Joy. Mr. Billington would, I am sure, be the last man to claim or appropriate another man's invention without acknowledgment, but as he was apparently not present at the reading of Mr. Joy's paper—at any rate, he took no part in the discussion—it is not surprising that Mr. Joy's slight misunderstanding should pass unchallenged.

As regards Mr. Basil H. Joy's remark as to the extreme delicacy of this packing and its great liability to injury, this appears to be due to the fine razor edge adopted in the modified form, which is entirely unnecessary. A moderate flexibility is all that is required, and for sliding surfaces of which the motion is only slow or occasional the result is entirely satisfactory, as is proved by the instance given in the "Proceedings" of the Institute of Civil Engineers already referred to, to which I may add that in Engine 147 of the Imperial Government Railways—Messrs. Dubs and Co., No. 2528—the same packing has been working for upwards of two years without any attention or adjustment, and is now to all appearance as good as ever. Whether it would be equally successful for the packing of a piston or piston-rod is, of course, another question altogether. I may add that my communication to the Institute of Civil Engineers was dated December 6th, 1892. The first engine to which my packing was applied had its valves altered here July, 1892. The first batch of engines built in England with my balanced valves and metallic U-packing was made by Neilsons and Co., quickly followed by Messrs. Beyer and Peacock, Dubs and Co., and Nasmyth, Wilson and Co. The first of these was ordered December, 1892. John McDonald, M.I.M.E.,

Assistant Engineer, Imperial Government Railways.
Shenbasi, Tokio, Japan, November 14th.

(*For continuation of Letters see page 578*)

## RAILWAY MATTERS.

A PORTION of the Oussouri section of the Trans-Siberian Railway between Vladivostock and Mouraviewa Amoursky, a distance of 235 miles, was opened for traffic on December 20th.

IT is expected that the Mushkaf-Bolan Line, of which we gave particulars in our issue of 13th July last, will be completed in July, 1895. This does not refer to a second line of rails which is in contemplation.

A LINE to facilitate the coke traffic between Durham and the West Coast is under consideration, the scheme being to connect Hincaster, on the Furness line, to Hawes, thus giving direct communication with Darlington.

THE Furness Railway Extension from Barrow-in-Furness to Bardsee will join the main line about two miles below Ulverston. This line will obviate difficulty hitherto met with in the conveyance of mineral traffic, as it is almost entirely level.

THE construction of a railway between Hiroshima and Shimonosaki has been sanctioned by the Japanese Government. In addition to these, lines will be constructed to connect, firstly, Sasebo and Tsukayaki; and, secondly, Kumamoto and Mesumi. The first-mentioned of the above will be a branch of the Sango Railway—110 miles long; the estimated cost being 3,000,000 dols.

THE route of the proposed new railway from Bristol to London *viâ* Bath is over the Midland line from Bristol to Bath, where several streets would be crossed by viaducts, thence under and over the Great Western Railway, and, passing through a tunnel under the hills on the south-east side of Bath, emerge into Wiltshire at Limpley Stoke, and continue past Trowbridge on to Waterloo.

A DEPUTATION from Masham, including the Right Hon. Lord Masham, of Swinton Park, a few days ago waited upon the directors of the North-Eastern Railway Company at York to ask them to extend the line from Masham to Bedale, a distance of about seven miles. It was asserted that this would make a direct route from Mid-Yorkshire to the West Coast and Scotland, and could be very cheaply worked.

IT is stated that the Boards of the South-Eastern and London, Chatham, and Dover Railway Companies have arranged to revise the passenger fares between all competitive points, and on their system generally, so as to bring them more into conformity with the scale of charges for the respective classes of passengers which for a long time past has been in operation on the lines of the principal railways having their termini in London. This revised scale of fares will take effect on and from the 1st of January next.

THE following instances of electric railway development in Switzerland are given by the *Electrical Engineer*:—"It is proposed to construct an electric tramway from Interlaken Railway Station to Gsteig-Wilderswyl. Power will be taken from the central electricity works at Interlaken. A scheme is also on foot for an electric tramway from Schwyz to Brunnen, Axenstein, and Schwyz to Seewen. It is proposed to establish an electric tramway between Zofingen and Aarburg, current being obtained from the central station at Ruppoldingen.

THE Government of India having sanctioned a detailed survey being undertaken for a line of railway from Arsikere, *viâ* Hassan, to the port of Mangalore on the West Coast, the work has been placed under the control of the Madras Government, and the project will be designated the Arsikere-Mangalore Railway Survey. Another survey has been approved by the Government of India, which is intended to connect Tinnevelly with Quilon. The work will be undertaken on behalf of the Travancore Government, and the project is to be styled the Tinnevelly-Quilon Railway Survey.

THE death is announced of Mr. John Dent Dent, of Ribston Hall, near Knaresborough, the chairman of the North-Eastern Railway Company, and one of the directors of the Forth Bridge Railway Company. He was born in 1826, was educated at Eton and Cambridge, and was called to the Bar in 1851, but did not practice. He entered Parliament for Knaresborough in 1852, and became member for Scarborough in 1857, and with the exception of one short Parliament, sat for the latter borough till 1874. He succeeded Mr. George Leeman as chairman of the board of the North-Eastern, and on the whole has shown much ability in his oversight of its affairs.

THE Great Eastern Railway Company has been approached by Cambridgeshire landowners and farmers, who offer to provide the land and money for the construction of a light railway provided the company works it. After inspecting the district, which is a purely agricultural one with a sparse population, the directors conclude to make the railway themselves and work it, provided they get the necessary land at ordinary agricultural values, and that it shall be for the carriage of goods only. There will be no signals upon it except at the junction with the main line, and the necessary staff and engine power will be small. The line will run through a very rich district of the Fen country. If successful this example will no doubt be followed in many other parts of the country. The Bill will come forward next session.

WE read of a rather curious accident to a goods train on the Southern Mahratta Railway at Alandi station, fifteen miles from Poona. *Indian Engineering* says: "The goods train was on the way from Miraj to Poona. If left Rajewadi all right, but before it reached Alandi and after it had ascended the ghauts, the train somehow parted about the middle into two, without either guard or driver noticing it. The driver went on with the second half, the train running down the incline of the ghauts in pursuit of the first half. The driver pulled up on its arrival at Alandi, and as soon as he did so, the second half smashed into him, completely wrecking four wagons, and damaging others, and blocking the line for several hours. A relief train was sent out from Poona immediately the news was received. The mail train from Bangalore could not get through with the mails, the passengers having been transhipped into a mixed train. The mail train from Poona to Bangalore had passed through Alandi before the accident happened."

THE North-Western Railway of Switzerland has had a number of simple and compound locomotives built by the Winterthur shops; they are identical in all parts, with the exception that in the compound engines the normal cylinder on the left side, which is 15¾in. in diameter, is replaced by a cylinder 22⅞in. in diameter, taking steam from the right-hand cylinder by way of a pipe passing through the smoke-box. To facilitate the starting, an inner starting valve is used, which allows live steam to be admitted directly into the large cylinder when the throttle valve is opened. The object of this identity in the construction of the engines is to permit of comparative tests being made of the consumption of fuel, which have been carried on for about nine months, starting in August, 1893, and extending through to April, 1894. For this purpose two types of engines were successively detailed to haul the trains for the same number of trips. Furthermore, the engine crews were transferred alternately from one to the other. In a word, the conditions of running were kept rigorously the same throughout the whole of this period. The average monthly run to each engine was 2625 miles, with an average train load of 21.17 axles loaded to 5 tons each. The consumption of coal has been taken from month to month, and has resulted in showing a gain of from 15 to 16 per cent. in favour of the compound locomotive. The *Schweizerische Bauzeitung* says that, under these circumstances, the company has decided to extend the use of these engines over its system, and has ordered six new ones rom the Winterthur shops.

## NOTES AND MEMORANDA.

IN determining the density of melted magnesia, M. Henri Moissan found that the density of this substance increases with the temperature up to bright red. It is thus that by heating in his electric furnace some magnesia, which is irreducible by heat, he has been able to vary the density from 3·193 to 3·654. This is all the more noteworthy, as this substance affords the only example of such a variation.

THE following is a proposed solder for use with aluminium or aluminium alloys invented by B. I. Roman. Silver, nickel, aluminium, tin, and zinc are mixed in the following proportions:—Silver, 2 per cent.; nickel, 5 per cent.; aluminium, 9 per cent.; tin, 34 per cent.; zinc, 50 per cent. No flux is necessary, and any soldering iron or tool may be used, though one of aluminium is said to be preferable.

IN a recent number of the *Comptes Rendus* is a paper on "The Determination of the Molecular Weight of Liquids," by M. Ph. A. Guye. The author gives methods of determining molecular weights of substances from a knowledge of their critical coefficients and molecular refractions, and from their critical coefficients only. The relationships for a number of hydrocarbons are given, and the deduction is drawn that these hydrocarbons have the same molecular weights in the gaseous state, in the critical state, and in the liquid state.

THE Welsbach lamp has a large number of German competitors. The price in Germany has been maintained above 15s.; in Frankfürt it has stood at 20s. The Gautzch burner costs 10s., and the new lamp of the International Gas Glow Light Company will cost 12s. to the trade. The last-named is stated to be the most durable lamp. All three consume about the same quantity of gas. The last-named gives somewhat less light, but the greater durability may make up for this in the estimation of consumers. The firm of Elster, Berlin, is, according to the *American Manufacturer*, about to put a new incandescent lamp on the market. It is not yet known whether this is the Butzke patent, or something different.

IN a paper recently read before the Royal Society on "The Effects of Mechanical Stress on the Electrical Properties of Metals," by J. H. Gray and J. B. Henderson, we read that the density of a well-annealed copper wire of 98 per cent. conductivity, decreases about ½ per cent. if stretched 25 or 26 per cent. A lead wire also decreases about ½ per cent. just before breaking. A copper wire drawn through twelve holes of a draw-plate increases in density more than 1 per cent. A manganese-copper wire—10 per cent. of manganese—increases in density about 1 per cent. when drawn down to half its former diameter. Twisting causes copper to increase about ½ per cent. for 2·3 turns per cm. Heating the above wires causes no appreciable alteration. Hammering a copper wire increases its density about 0·2 per cent.

AT a recent meeting of the Cambridge Philosophical Society a paper on "A Model of the Twenty-seven Lines on a Cubic Surface" was read by Mr. W. H. Blythe. Mr. Blythe exhibited a model of the twenty-seven straight lines on a cubic surface, together with the drawings from which it was constructed. He stated that the 135 points of intersection of these lines can, in a special case, be determined by a simple geometrical construction without reference to any equation. Seven points taken at random on the edges of a tetrahedron are sufficient to give values to all necessary constants, and these points acting as pointers by pairs, fix the position of eleven other points; these eighteen points being used to determine others, and so on. This method *Nature* says, is also applicable to the general case, but determines fifteen lines only; when, however, the sixteenth line or one point on it is fixed by a process of adjustment the remaining points can be found in the same way.

A PAPER on "Researches on the Condensation of Electrolytic Gases by Porous Bodies, particularly by metals of the platinum group; Applications to the Gas Battery; Electric Accumulators under Pressure," was recently read before the Paris Academy of Sciences by MM. Cailletet and E. Collardeau. Platinum and palladium in the spongy condition, and ruthenium iridium, and gold in the finely divided state, form poles which condense electrolytic gases, and hence produce a gas battery, on subsequent connection of the poles, capable of giving up the stored energy during a short time. The storage capacity may be vastly increased by subjecting the poles to great pressure during charging. With spongy platinum and iridium a storage capacity may be attained greater than the practical capacity of lead accumulators per unit weight. Silver, tin, nickel, cobalt, and carbon do not form accumulators under these conditions with capacity increasing with the pressure.

A PATENT has been recently granted for an aluminium alloy consisting of copper, tungsten, aluminium, tin, and antimony, for either of the two latter manganese or nickel being at times substituted. The proportions preferred are somewhat as follows, expressed in percentages:—Copper, 0·375; tin, 0·105; antimony, 1·442; tungsten, 0·038; aluminium, 98·040. Tungstic acid and cryolite are melted together, equal proportions being employed. When the temperature reaches 1200 deg. C., aluminium is added so as to produce a 10 per cent. compound of aluminium and tungsten. A second alloy is made containing equal proportions of aluminium and copper. These two alloys are then melted together with pure aluminium in the proper proportions to form the alloy required as above; tin, antimony, or their substitutes being added in the necessary proportions, or they may be left out altogether when the copper and tungstic acid originally employed are chemically pure.

THE processes ordinarily used for covering metals with zinc, tin, and lead have not, up to the present, appeared to be applicable to aluminium. When a plate of aluminium, mechanically or chemically cleaned, is immersed in melted tin, zinc, or lead, these metals slide over the surface of the aluminium without alloying therewith. *Le Genie Civil* says that M. Oliven has found that, in order to fix the above-named metals, it is necessary to submit the surface of the aluminium to a vigorous brushing in the metallic bath. For this purpose a steel brush or any other analogous instrument may be used. Under these conditions the aluminium becomes covered with a regular layer of the molten metal. The want of success of the operation was due, it appears, not to the want of affinity of the aluminium for the metals in question, but to the immediate formation in contact with the air of a thin stratum of oxide of aluminium, which can be removed by friction.

MR. E. G. ACHESON, the inventor of carborundum, has recently produced a carbon for which he claims high fusing point combined with high luminosity. He takes pure carbon and carbide of silicon—carborundum—reduces both to fine powder and mixes them in the proportions of nine parts of the former to one of the latter, together with tar or any other good binding material. The mixture is then baked and moulded into the proper form for use. In order to get the full and complete effect of the illuminating qualities of the carbide of silicon more distinctly separated from that of the carbon, the ordinary cored carbon rod or point is used and the core is filled with the carbide of silicon, either alone or with a binding agent. For the filaments of incandescent lamps, the carbide of silicon in a very fine powder is mixed with and suspended in the oil used in the oil bath, for the treatment and building up of the carbons; and in the process of depositing the carbon from the oil bath on to the filament, the fine particles of carbide of silicon become fixed to the filament simultaneously with the deposit of carbon.

## MISCELLANEA.

MESSRS. JOSEPH EVANS AND SONS, Wolverhampton, announce that they have appointed Mr. R. H. Longbotham, of Bank Buildings, West Gate, Wakefield, as their Yorkshire agent.

THE Bethlehem Iron Co., Pennsylvania, has been awarded the contract for armour-plates for the new Russian warships Sebastopol and Petropavlovsk, the estimated value being four millions of dollars.

IF experiments at present being made on H.M.S. Indefatigable with armament altered so as to lighten her bow and stern ordnance are successful, all the cruisers of this class will undergo a similar change.

WE are informed that Mr. Frederick J. Marshall has retired from the firm of Ransome and Marshall, of Liverpool, and that the business will be carried on under the same style and title as heretofore, by the remaining partner, Mr. G. Frederick Ransome.

ANOTHER torpedo boat destroyer has been launched, this time by Mr. T. S. White, of Cowes. She is named the Conflict, and her length is 205ft. 6in., beam 20ft., depth 11ft. 6in. Mr. White's turnabout system for quick manœuvring and water-tube boilers are to be fitted.

MESSRS. COMYN CHING AND CO., Castle-street, Long Acre, have received orders to provide and fit the extensive steam and gas cooking apparatus for the kitchens in the new Post-office Buildings in St. Martin's-le-Grand, on the same principle as already supplied by them at the new Parcel Post Depôt, Mount Pleasant.

MESSRS. WILSON HARTNELL, of Volt Works, Leeds, and John A. Edmondson announce that they have amalgamated their separate businesses and entered into partnership as engineers and contractors, to trade under the style of Wilson Hartnell and Edmondson, but they also announce that they will continue to practice as consulting engineers.

NAVIGATION in frozen waters is, according to a recent Dutch patent, to be made possible by using saws mounted on an extension in front of the vessel, under the ice, which are driven by an engine on the vessel, the cut ice being collected in a chamber, from whence it is delivered under the unbroken ice at the sides of the passage thus formed. The inventor is J. J. Van Leeuwen, of Arnheim, and the builder J. A. Kruisbrink, Amsterdam.

A RECENT Admiralty circular directs that Temperley transporters shall be in charge of the engineer department. It was generally thought once that these would be included in the boatswain's stores, but we have always considered this unlikely, as we know well that wherever extra care and responsibility is involved, the unfortunate engineer officers always come in for it.

A MEETING of gentlemen has recently been held in Glasgow to consider the proposal of establishing an engineering laboratory for Glasgow University. Professor Barr explained the scheme, and in suggesting the appointment of a committee, advocated the bringing of the applied science department of the university into closer touch with the engineering practice of the district. Subscriptions have been raised to the amount of £3750.

MESSRS. GEORGE ELLIOT AND CO., of the Patent Wire Rope Works, Cardiff, announces that Mr. John I. Hopper, in whose name their works at Tyne Docks have been carried on for seventeen years, is retiring from the management on December 31st inst., and for the future the business will be conducted under the direct control of George Elliot and Co. from 16, Great George-street, London. Mr. A. G. Laker will be the manager at the works.

THE high-angle fire gun mountings of the Centurion and Barfleur are said to be giving satisfaction. The system finds favour on account of its independency of steam or hydraulic power. The Centurion's heavy guns, for instance, can be manipulated by hand with perfect ease, while in the Barfleur electro-motors are employed. The use of the latter in connection with these mountings will probably be extended. The 10in. breech-loaders of H.M.S. Renown will be fitted with these mountings.

WE have received from Mr. Henry Simon, milling engineer, of Manchester, a very handsome Calendar for 1895, with a "tear-off" for each day in the year, printed with large figures and letters, each day having a motto; which, judging by the Calendar of last year, will be an interesting feature. We have also received from Messrs. E. R. and F. Turner a handsomely prepared "tear-off" Calendar, the background of which carries Calendars for the whole year, and is illustrated with engravings of a few of Messrs. Turners' special milling machinery. The Magnolia Metal Company also send a handsome Calendar sheet.

RECENT Glasgow intelligence is to the effect that on the morning of the 15th inst. eighteen men were entombed in a subway a quarter of a mile from the outlet, in St. Enoch's-square. As smoke was issuing from the shaft the fire brigade was summoned. Six of the eighteen men were got out immediately, but the other twelve could not be reached. The workmen in the parallel iron tunnel communicated with them by knocking. The sides of the two iron tunnels were forced open after six hours' work, and the twelve men rescued safely. The air-pumps worked well, so that the men breathed freely. The fire arose from the ignition of the woodwork of the air lock. The tunnel passes under the river, and on to the south side of the Clyde.

A DESCRIPTION of a heavy fly-wheel composed of wire appears in the *American Manufacturer* as follows:—"Amongst the most recent and novel applications of wire, perhaps none has greater interest to the mechanical world than that presented by the new wire fly-wheel lately erected at the Mannesmann Tube Company's Works, Germany. Heavy fly-wheels driven at high velocities obviously present dangers of breaking asunder from the great centrifugal force developed. The wheel at the factory mentioned consists of a cast iron hub or boss, to which two steel plate discs or checks, about 20ft. in diameter, are bolted. The peripheral space between the discs is filled in with some 70 tons of No. 5 steel wire, completely wound round the hub, and the tensile resistance thus obtained is far superior to any casting. This huge fly-wheel is driven at a speed of 240 revolutions per minute or a peripheral velocity of about 2·8 miles per minute, which is nearly three times the average speed of any express train in the world. The length of wire upon such a constructed fly-wheel would be about 250 miles."

AFTER many experiments, extending over fifteen or twenty years, the Amu Darya, or Oxus, has at last been safely navigated by the Russians as far as Faizabad Kali, on the Afghan frontier. A vessel of the Amu Darya flotilla, the steamer Tsar, under the command of Admiral Baturin, reached a point close to the ruins of the Faizabad Fort, after passing the junction of the Kafirnahan river with the Amu Darya, on October 14th, sixteen days after leaving Karki. The steamer towed a barge behind it as far as the mouth of the river Surhani, where it halted to take in naphtha fuel. The navigable channel between Karki and Kilif was found to be incomparably wider than that between Karki and Charjui, and the depth of water was nowhere less than 4½ft. Beyond the mouth of the Surhani, however, there were only 4ft. of water, and the further progress of the steamer beyond Faizabad in the direction of the Pamir frontier was barred by the fact that the depth decreased to 3ft. The St. Petersburg correspondent of the *Times* says that no boat has ever before made its way so far up the great, but shallow, stream of the ancient Oxus.

## TO CORRESPONDENTS.

**Registered Telegraphic Address, "ENGINEER NEWSPAPER LONDON."**

*** *All letters intended for insertion in* The Engineer, *or containing questions, should be accompanied by the name and address of the writer, not necessarily for publication, but as a proof of good faith. No notice whatever can be taken of anonymous communications.*

*** *We cannot undertake to return drawings or manuscripts; we must therefore request correspondents to keep copies.*

*** *In order to avoid trouble and confusion, we find it necessary to inform correspondents that letters of inquiry addressed to the public, and intended for insertion in this column, must in all cases be accompanied by a large envelope legibly directed by the writer to himself, and bearing a penny postage stamp, in order that answers received by us may be forwarded to their destination. No notice can be taken of communications which do not comply with these instructions.*

An Outsider.—*We fail to see that your long letter adds anything useful to the discussion. We have already explained why it is that modern locomotives weigh so much more than their predecessors. The cost of repairs and the loss by engines standing idle are thereby reduced. This consideration you and several other correspondents entirely ignore. Whatever you may think about locomotives and firemen, the fact remains that some days engines steam much worse than usual, from causes which no doubt exist but are not known.*

W. G. W. (Dunardagh).—*If the ship is at rest the torpedo will go straight if the controlling gear in the torpedo itself be properly balanced. Some torpedoes have a certain amount of deflection, which is known and can be allowed for. If the ship is going ahead there will be also a certain amount of deflection due to the direction and speed of the streams of water relative to the ship. Allowance has to be made for this by the officer who fires the torpedo, and as the result of a great number of experiments this can be allowed for with a fair amount of accuracy.*

**SUBSCRIPTIONS.**

The Engineer *can be had, by order, from any newsagent in town or country at the various railway stations; or it can, if preferred, be supplied direct from the office on the following terms (paid in advance):—*
*Half-yearly (including double number)* .. .. £0 14s. 6d.
*Yearly (including two double numbers).* .. £1 9s. 0d.

*If credit occur, an extra charge of two shillings and sixpence per annum will be made.* The Engineer *is registered for transmission abroad.*

*A complete set of* The Engineer *can be had on application.*

*In consequence of the reduction of postage on newspapers to one uniform rate for any destination outside the United Kingdom, Foreign Subscriptions will, until further notice, be received at the rates given below. Foreign Subscribers paying in advance at these rates will receive* The Engineer *weekly and post free. Subscriptions sent by Post-office Order must be accompanied by letter of advice to the Publisher.*

Thin Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £0 18s. 0d.
*Yearly* .. .. .. .. .. .. .. .. .. £1 16s. 0d.
Thick Paper Copies—
*Half-yearly* .. .. .. .. .. .. .. .. £1 0s. 3d.
*Yearly* .. .. .. .. .. .. .. .. .. £2 0s. 6d.

Reading Cases.—*The Publisher has in stock reading cases which will hold thirteen copies of* The Engineer. *Price 2s. 6d. each.*

**ADVERTISEMENTS.**

*** *The charge for advertisements of four lines and under is three shillings, for every two lines afterwards one shilling and sixpence; odd lines are charged one shilling. The line averages seven words. When an advertisement measures an inch or more, the charge is ten shillings per inch. All single advertisements from the country must be accompanied by a Post-office Order in payment. Alternate Advertisements will be inserted with all practical regularity, but regularity cannot be guaranteed in any such case. All except weekly advertisements are taken subject to this condition.*

*Prices for Displayed Advertisements in "ordinary" and "special" positions will be sent on application.*

**Advertisements cannot be inserted unless delivered before Six o'clock on Thursday evening; and in consequence of the necessity for going to press early with a portion of the edition, ALTERATIONS to standing advertisements should arrive not later than Three o'clock on Wednesday afternoon in each week.**

*Letters relating to Advertisements and the Publishing Department of the paper are to be addressed to the Publisher, Mr. Sydney White; all other letters to be addressed to the Editor of* The Engineer.

## MEETINGS NEXT WEEK.

Geologists' Association.—Friday, January 4th, at University College, Gower-street, W.C., at 8 p.m. Paper: "On the Analysis of Oölitic Structure," by George F. Harris, F.G.S., and will be illustrated by the oxyhydrogen lantern.

## DEATH.

On December 22nd, suddenly, of heart disease, Edward John Lloyd, M.I.C.E., of Hatton Hill, Warwickshire.

# THE ENGINEER.

*DECEMBER* 28, 1894.

### RAILWAY EXTENSION IN CEYLON.

They appear to manage their railway matters after a somewhat singular fashion in Ceylon. At the very time that the Government and railway companies in India are endeavouring to extend the system of feeders for their main lines, we hear that the latest extensions made in Ceylon have been opened with their stations almost unprovided with means of access to them. According to the *Ceylon Observer*, more than one of these stations have not even an ordinary road of approach. The consequence is—as might well have been foreseen—that the produce of many estates, the proprietors of which would gladly have availed themselves of railway facilities, is being sent by carts to the sea for shipment on the east coast of the island. Thence this is carried in small coasting steamers to Colombo on the west coast, whence it is dispatched by larger vessels to Europe. And yet these estates are situate within a few miles only of direct railway communication with the port last named; but this, owing to the circumstance indicated, remains unused, and a heavy loss must follow to the railway revenue.

Now railways in the mountainous districts of Ceylon are exceedingly costly things. Few regions of the world more severely tax the skill of the engineer for their construction or demand a greater outlay per mile. It would only seem to be natural, therefore, that roads to feed these lines should be constructed in advance of opening them for traffic. The Ceylon Government would appear to have a different conception of its duty, and to prefer "putting the cart before the horse." We have referred to the activity with which India is bestirring herself in the matter of feeding her main systems of railway. Evidence was very lately adduced that in the case of the Bombay and Baroda Railway Company, the exceptionally favourable condition of its finances is largely to be attributed to the energy with which its directors have exerted themselves in this direction. The Eastern Bengal Railway Company having determined upon following so profitable an example, has lately, we believe, added half a million sterling to its capital for this express purpose; while the Indian Government seems at length to be fully alive to the necessity for offering every encouragement to enterprise of a similar class. But it would seem to be the speciality of Ceylon to progress backwards—or at least to remain stationary — whenever India sees fit to go forward. There seems to be nothing more desired by the Colonial Government than to pose in every way as the antithesis to that of the adjacent continent. Any proposal put forward whereby the systems, administrative or fiscal, are likely to approach assimilation, is regarded with disfavour by the rulers of the colony. We have seen, for instance, extensive conversions of the former Indian railway gauge of 5ft. 6in. to a narrower type. It seems natural to the Ceylon Government, as the consequence of a desire for contrast, not only to adhere to that standard throughout its main systems—which was perhaps to be justified—but to contemplate running new lines of this abnormal gauge through wild and almost uninhabited districts to the further extremities of the island. With equal determination does it resent the proposal made to it to connect its territory by railway with that of India. The bare idea of becoming one, even to that extent, with its dreaded neighbour, appears seriously to affect the composure of its rulers.

One would have thought that the little colony would have rejoiced at all opportunity for closer intercourse with India. It is from thence that it obtains all the labour required for its great industry, while the larger proportion of its resident population is dependent upon imports of grain from the vast rice fields of India for its daily food. And yet, because India approves and supports the project of railway connection between the two countries, the administration in Ceylon does all it can to throw cold water upon it. The fact would cause us much surprise were we not aware of the idiosyncrasy to which we have alluded. This is of modern date, because there has recently been published evidence proving how thoroughly in accord were the Governors of Ceylon and Madras of a former period upon questions affecting the interest of the two provinces. It is to be feared that the latest extension made of the great hill railway of Ceylon must detract from rather than add to its profitableness. Should this result, we should perhaps hear more as to the unaccountable policy that has left stations without means of access, and compelled traffic to seek different outlets while the means for ready communication with the seaboard had been brought, relatively speaking, almost to the planters' doors. This unpleasant experience must, we should say, impose upon the Colonial Office the duty of asking how such things can be in a Crown Colony hitherto so progressive as Ceylon. It is not as if there was any narrowness of means to urge in excuse of so short-sighted a policy. While the railway constructed at so large a cost is being starved for the want of roads of approach to its stations, large sums are assigned for the restoration of ancient tanks, the justification for which has been extensively contested. With this last point, however, we have little to do. But we feel that the future of railway extension in what is perhaps the most important of our Crown Colonies must be seriously imperilled by a policy so extraordinary as that disclosed by the *Ceylon Observer*. Practically that policy has been to expend a very large sum on a railway, and while doing so to take every precaution that it shall have no chance of affording a remunerative return for the outlay made upon it. If we may accept this proceeding as typical of the influence now at work in Ceylon to retard her progress, we should say that the sooner some action in the direction of change is resolved upon by the Colonial Office the better it will be for the colony.

### STREET PAVING AND HYGIENE.

Asphalte for the public and wood for the horses fairly represent the general distinction we have drawn on previous occasions respecting the qualifications of these two descriptions of street paving. This line of demarcation which is becoming more apparent every day, assigns the former material to the pedestrian, and the latter to the vehicular traffic of the principal thoroughfares of the metropolis, and other cities of proportionate magnitude, importance, and population. Granite pitching is regarded as inadmissible for reasons with which we are not concerned in the present article, as a future method to be employed. A notable instance, nevertheless, of its use on a tolerably extensive scale, is afforded by the recent repaving of Blackfriars Bridge, and the torture to which the unfortunate horses are subjected in endeavouring to make good their footing on its slippery surface is deplorable, and a disgrace to the people of the most humane nation on the face of the globe. If we consider stone setts as out of the question, it is difficult to discover what other systems are left to us, after the sweeping denunciation of all macadamised roads by Sir Robert Rawlinson in his presidential address to the Institution of Civil Engineers. The president observed that the Thames Embankment was "a grand metropolitan improvement spoiled with broken stone. So many thousand tons of broken stone were carted on annually; so many thousand tons of mud, when it has done all the mischief possible, to be carted off. Macadam roads in London streets and squares should be abolished."

Those who have watched patiently and attentively, the operation of the re-metalling of any particular length of our riverain boulevard; will probably be inclined to agree with the remarks of Sir Robert, so far as that especial thoroughfare is concerned. But we doubt whether they will altogether endorse the wholesale condemnation of a method of street-making which, whatever may be its failings or deficiencies, possesses features of undoubted merit under certain conditions of traffic and maintenance. Our object at present is not, however, to inquire into or discuss, except indirectly, the relative merits from a purely traffic point of view of the numerous systems of street paving which have been experimented upon and laid down during the last thirty years or more in the main streets and roads of London. Timber, stone natural and artificial, iron cast and wrought, and almost every constructive material, have had a fair trial allowed them at different times, and yet how few have proved themselves to be endowed with the qualities indispensable for the purposes they were intended to fulfil. Our climate, it must be admitted, is terribly trying to every description of road and street paving which has to fulfil its duty in all weathers and under all circumstances. An essential requisite is that the surface should be easily cleaned. It should also be not reticent or absorbent of putrescible matter, either in the material itself or in the joints, presuming a system is employed entailing joints. These are points requiring and deserving close attention, for when we regard the large areas which are covered by paving, it is obvious that their sanitary or insanitary condition, or even tendency, becomes a serious question of public hygiene.

It is now some years since our own engineers, scientists, and sanitary authorities, as well as their professional *confrères* in France, Germany, and the United States, commenced a grave investigation respecting the probable dangerous results which might accrue to the health of the general community, by an indiscriminate employment of wood paving. Without entering into details which, no doubt, vary more or less in each particular case, the usual process of construction is familiar to most of us; but the effects, and the manner in which they are produced, are not so well known, and in a question of so much interest and importance a brief description will not be out of place. Upon a bed of Portland cement some 7in. or 8in. in depth are truly and accurately laid the wooden setts or blocks, which are either creosoted or dipped in boiling tar as a rule, but not always. At Charing Cross plain wood was used. Whether close-jointed or set with joints from ¼in. to ⅜in. in thickness, the whole surface is grouted with cement grouting. A blinding of sand is distributed as a top dressing, and the roadway thrown open to traffic. At first the action of the wheels of the heavier carts and vans is to consolidate the roadway by forcing the particles of gravel into the pores of the wood, thus forming a protection for it against the injurious effects of external attacks. In this preliminary stage of its existence the wood paving leaves little to be desired. It presents an excellent surface for running on, is comparatively noiseless; inodorous; easy for the feet of the horses, and has the great advantage of seldom cutting their knees should they have the misfortune to fall. It is, in fact, the *beau ideal* of a roadway for vehicular traffic; but we must not dilate upon its merits in this respect any further. As already stated, our business at present is with the physical causes which, sooner or later, bring about a change in this preliminary satisfactory state of the paving, and are — or at any rate may be — attended with injurious results to public sanitation. Assuming that the blocks have been dipped in creosote or tar or some preserving fluid, the coating applied will for a time preserve them from the rain and wet, but this preservation is of a very ephemeral character. It must be borne in mind that the wooden blocks are frequently dipped only in the protecting liquid, and not subjected to any actual preserving process as is the case with railway sleepers, although even with them the depth of penetration is sometimes comparatively trifling. In other respects there is no analogy between the two examples. Railway sleepers have exceptionally heavy crushing loads to withstand, but there is no absolute attrition or grinding action of horses' feet and wheels upon them, as occurs with road traffic.

The opponents of wood pavement hold that it is evidently not long before the ordinary wear and tear completely destroys the protecting crust formed on the surface of the wooden blocks, and now the mischief begins. There is now little or nothing to prevent the fibres and pores of the wood from becoming saturated with rain water and other far more noxious liquids, which enter with facility and rapidity, but are expelled tardily and with difficulty, if indeed, they are ever altogether got rid of. The preserving crust once removed, two physical changes become at the same time unpleasantly in evidence. One is the development in dry weather of a very fine description of dust, composed of minute disintegrated particles of wood, and any other impalpable portions of deleterious ingredients to hand. This highly dangerous, almost invisible product is disseminated in the air we breathe, and it is not difficult to predict its effect upon delicate and sometimes unsound pulmonary organs. Again, owing to the repetition of the same cause, the blocks become more absorbent, and eventually become completely saturated with every impurity and element of foul matter belonging to street traffic which is capable of being held in mechanical suspension, or imprisoned in a chemical solution. These liquids carry with them into the pores of the wood putrescible matters which subsequently escape in the form of poisonous gases and miasma, into the atmosphere, to its serious contamination and deterioration. If these noxious germs penetrated no further than the setts themselves, and restricted their dangerous action to one of a comparatively superficial character, the evil might not be—at least to any great extent—of a permanent nature. But they find their way through both close and open jointed paving, and gradually work down until they reach the solid substratum of concrete, where they establish for themselves a resting place, and for the community a fruitful source of incessant insalubrity. The degree to which this pestilential saturation might attain would be abundantly exemplified by taking up the setts of any of the public cab and carriage stands. While, therefore, the evil is always present, its effects may be accentuated or mitigated by the position and general features of the locality. In large spacious thoroughfares well exposed to both sun and wind, the sources of infection might be dispersed and swept away almost as quickly as they were formed. But in narrow streets, fenced in by houses of a height which do not permit much sunlight to enter, which constitute fully three quarters of London, the pestilential agents at work encounter little or nothing to interfere with their septic activity.

Some fifteen years ago, not to go further back, a terrible epidemic afflicted the city of New Orleans, and carried off in a couple of months over 10,000 of the inhabitants. One of the Officers of Public Health in the States, a man of position and experience, gave it as his deliberate opinion that the extraordinary intensity and virulence of the disease was due to the foul gases and pestilential emanations arising from and disseminated by the wood paving of the town. We are willing to admit that the lethal progress of almost any epidemic would probably be accelerated—or, in any case, not arrested or retarded—by the presence of the evil alleged; but, in the absence of corroborating evidence or further proofs, which are not at our command, we decline to return a verdict of guilty on all counts against wood paving. It may be observed, in confirmation of the conclusion we have arrived at, that a very large part of the city of New Orleans is situated below the flood level of the Mississippi, and therefore it presents rather a favourable mark for the attacks of epidemics; and it must not be forgotten that the health of our metropolis has steadily improved, notwithstanding the spread of wood paving. Indeed, it is easy to see that both macadam, and stone paving with more or less open joints, are both partially open to the same objection as wood.

In a hygienic point of view, asphalte paving is absolutely unassailable. Its very constitution is antiseptic, and it is no wonder that it is a powerful rival to the wooden system. No people have been more severe upon the insanitary nature of wood paving than the Germans. One and all condemn it. They assert that the dust of the blocks, mingled with a host of putrescible matters, is fatal to the respiratory organs, and a constant source of painful coughs and even of phthisis. The result of this national consensus is to be found in the statement that a couple of years ago it was estimated that the total area of the wood paving in Berlin did not exceed 18 acres, while that of compressed asphalte attained to 190 acres. Our own authorities are not by any means all at one regarding this question. It is barely six months since the proposition to re-pave Upper Thames-street with wood was rejected on the ground of the absorbent nature of the material. It was also stated before the Commission of Sewers that, of all the systems of paving, that of wood was the most injurious to the public health. After what has been remarked, it might not unreasonably be asked, are we to abandon, as the people of Berlin practically have done, the system of wood paving which, in respects other than we have regarded it in this article, is endowed with many advantages? Neglecting for the moment the question of durability under wear and tear, it would naturally occur on reflection that the evils complained of with regard to wood pavement are the inevitable accompaniments of employing a soft description of timber, which, always of a spongy and absorbent nature, becomes more so under the action of the deteriorating external agents already enumerated. Is the remedy to be found in the use of a hard close-grained timber such as is laid down in Australia? Partially, very probably yes; but altogether, we think not. There must be a certain amount of elasticity or resistance in all roadways and footways, which are after all only particular examples of solid flooring. If the material be of a degree of hardness so excessive as to merge into brittleness, then it defeats the very purpose it is intended to serve. It by no means follows that a heavy hard timber, for example, the tallow-wood, the red mahogany—both of which belong to the genus Eucalyptus—or the turpentine or blackbutt, all of which are stated to afford excellent results in their native country Australia, would be equally successful in England, or would to any appreciable extent mitigate the injurious effects produced by our softer woods. If we add to the terrible severity of our climate upon all outdoor works, the enormous number of the horses and vehicles plying in London; their large individual weights; the pounding, abrasion, and attrition which they must exercise upon the heads of the blocks, it is scarcely possible that the surface of the roadway should remain impervious for any length of time to the noxious action of liquid impurities. There is, we believe, one very remarkable fact in indirect connection with our subject—that is, that whereas wood pavement has been repeatedly taken up to make room for the laying of asphalte, there is no example on the *vice versâ* side in the city of London, exempting always some experimental lengths permitted to be tried many years ago.

### TEXTILE MACHINERY FOR INDIA.

THE chief machinery imports entering India from England in connection with the cotton industry continue to be cotton machinery, engines and boilers, and shafting and gearing. The type of ginning machine in general use, it is pleasing to know, is the roller gin from England, though the saw gin from America is also employed there. A few years ago the roller gin was generally exported from Great Britain to India in a complete condition ready for working, but nearly all the ginning machines are now sent with bare shafts, and are covered with leather when they arrive out. We hear of a few cases in which only the frames of ginning machines have been ordered from British makers, with a well-known English firm's name cast upon them. The other parts, except the steel knives, have been made in Bombay and fitted to it. This has been done with the intention of selling the machine as an imported one at a somewhat lower price. The makers, however, found out what was going on, and declined to supply the framing only. A gradually increasing demand for ginning machinery is pretty certain to be experienced, and whether native manufacture will advance in that department or not, there are at any rate reasons for believing that as regards cotton presses, these will continue to be imported from England for many years to come. Almost entirely of English manufacture is the spinning and weaving machinery used in English mills, and it is likely to remain so for a long period. The Bombay firms seem at present content to be able to supply parts in cases of breakdown. We cannot agree with those who hold that the demonetisation of silver will increase the demand for machinery for India, China, Japan, Mexico, and other silver using countries. Statistics do not support this view so far. In fact, the increased silver cost of the plant tends to promote native manufacture. Somewhere about £80,000 a month is the normal value of the Indian imports of British textile machinery. Just now we are a little under the average. With reference to engines and boilers, there is no disguising the fact that some of the smaller kinds of engines are being increasingly made in Calcutta, Madras, Bombay, and other Indian towns, though England still retains the supremacy for motors of high power.

### THE TRUTH ABOUT BELGIAN COMPETITION.

A NEW light has been shed on the question of Belgian competition by the recently issued report of the Charleroi Ironmasters' Association. This body expresses surprise that the members of the British iron trade should take so serious a view of Belgian competition with English manufacturers, and they declare their desire to correct several false impressions which they say seem to have got abroad in England on the matter. Especially they feel hurt—and no wonder—at the suggestion that English trades' unionists should be sent across to raise Belgian wages to the English level, so as to stop competition. It is clear from their report that whatever may be the case as to their trade dealings with ourselves and with our foreign customers, they have as much as ever they can do to make a profit. In a word, they are not such formidable competitors as they have been made out to be—a truth which we have long since insisted upon in these pages. Low wages, they declare, are made up to their men by the very cheap continental food and clothing. The English opinion of rock-bottom Begian railway rates it seems is all a mistake—or next door to it. The 4f. 46c. per ton for Charleroi iron sent from Liège to Antwerp, which was the sheet anchor of those who wished to prove the great advantages enjoyed by our neighbours, has given way, since it now appears that the great bulk of the iron and steel manufactured at Liège is sent to Antwerp by rail at a very much higher rate of freight. The average cost of coal at the pit mouth in 1893 was 7s. 6d. a ton, or higher than in either England or Germany, and the profit was only 3d. per ton. In fact, the historic treatise upon "English as she is spoke" does not, we are fain to believe, convey a more faulty impression of the British tongue than do the reports lately brought home by the Iron and Steel Institute members of the state of the Belgian iron and steel trades.

## LITERATURE.

*A Text-Book of Ore and Stone Mining.* By C. LE NEVE FOSTER, D.Sc., F.R.S. 8vo, pp. 744. With illustrations. London: C. Griffin and Co. 1894.

THIS volume, whose object is to assist students in acquiring a knowledge of the art of mining, is a notable addition to the literature of a subject which is but scantily represented in this country. The author, combining his long experience of our home mines as a principal inspector of mines under the Metalliferous Mines Act, with that obtained in his numerous visits to those of foreign countries, has been able to bring together a large series of examples of the methods of stone and ore mining in use at the present time in different parts of the world. The subject of coal mining has been excluded, as that subject has been treated by Mr. H. W. Hughes in a companion volume published at an earlier date. The order of arrangement adopted is similar to that generally used in systematic treatises, the mode of occurrence of minerals taking the first place, and being followed in due order by descriptions of the methods of prospecting, boring, sinking, and driving, and so on to the thirteenth chapter, which is devoted to the consideration of the various processes employed on the dressing floor for making merchantable the minerals got in the mine. These are supplemented by chapters on economic and social matters—such as the systems of payment for mining labour, accidents in mines, the clothing and housing of miners, and a general view of the legislation affecting mines and quarries in the United Kingdom. This order—which, we believe, is that followed by the author in his lectures at South Kensington—is certainly well suited for promoting the methodical arrangement of ideas among students; and the value of the book as a guide to reading is much enhanced by the full and careful manner in which the references to the authorities quoted are given.

In the first and, with one exception, the most important section of the volume—that on the method of occurrence of minerals, which is only exceeded in extent by the chapter on dressing—the different types of mineral deposits are described and illustrated by examples from some of the most prominent of the great mines of the world—such as Hecla and Calumet, Mount Morgan, Rio Tinto, and the Kimberley Diamond Mines.

In defining the terms descriptive of mineral deposits, the author expresses himself very decidedly against the use of the term "gangue" for valueless constituents in a mineral lode; but he seems to have missed the most expressive of all the equivalents—namely, "waste." "Veinstone" and "lodestuff" seem to be more appropriate to the whole of the vein-filling—*i.e*, to ore and waste as they occur together, rather than to the latter alone. In the sections on breaking and securing ground, the newer developments in boring machinery, the use of metal props and arching in levels, and the methods of sinking through difficult ground by boring and tubbing, as well as by the use of the Poetsch and Gobert systems of freezing watery strata, receive notice in regular order, the first of these subjects especially being very fully treated. In these, however, as in the chapters on ventilation and lighting, and, indeed, in many other places, the dividing line between ore and stone, and coal-mining, has been so frequently overstepped, that we are forced to the conclusion that it would have been better had the conventional division been more completely disregarded, and the methods of working stratified mines been more thoroughly treated. As it is, some of the examples seem to be decidedly out of place, as, for instance, the large pit tram—Figs. 412-418—7ft. long, with spring drawhooks and other refinements, intended to carry two tons of coal, and weighing 52 cwt. loaded. Such a vehicle could only be used under very special circumstances even in a colliery, and in any average lead or tin mine it would be a very strange monster indeed. On the other hand, several characteristic specialities of metalliferous mines receive but scanty treatment, and one of them, the use of water power in direct-acting pumping engines, is entirely omitted.

The dressing and preparation of minerals are very fully treated in Chapter XIII., exactly one hundred pages being devoted to the consideration of the different operations involved in this very comprehensive term. It includes notices of crushing, grinding, sizing, and separating machines of all kinds, from the well-abused old stamps to the more refined centrifugal and other rotating mills, which are, mechanically, more efficient, but, somehow or other, seem to display that efficiency best on bones, chalk, phosphates, and similar substances, leaving the more severe business of quartz and tin-stuff crushing to the rougher contrivance of the past. Magnetic separators, as developed in Sweden, America, and elsewhere, receive a considerable amount of attention, but we should have liked in connection with this part of the subject to have had some more information as to the actual value of such contrivances. If we remember rightly, the general impression upon the visitors from this country, who saw these machines at work in America in 1890, was that they might be useful in gleaning over the waste of old workings, but that it would be scarcely worth while to be at the charge of mining fresh stuff to keep them at work. The amount of power also seemed in most cases to be rather large in regard to the work done.

The work is profusely illustrated. The frontispiece, representing a stope at the 274 fathom level in Carn Brea, is reproduced from one of Mr. Burrows' photographs taken underground in Cornwall, while the figures in the text are drawn from a great variety of sources, and, therefore, of variable degrees of excellence; most of those illustrating mining works are good, whereas those of machinery are often much the reverse. Figs. 544 to 550, illustrating a pumping plant in the Forest of Dean, are especially bad, and altogether unworthy of the character of the book. We suppose, however, that these may fairly be considered to be the shortcomings of the publisher rather than the author.

---

*Select Methods in Chemical Analysis.* By WILLIAM CROOKES, F.R.S. Third edition, rewritten and enlarged. Large 8vo, pp. 718, with 67 woodcuts. London: Longmans, Green, and Co. 1894.

A NEW edition of this well-known volume having been called for, the work has been gone over, and many additions recording the changes and improvements in inorganic analysis made during the past eight years have been made; and to find room for these without unduly increasing the size of the book, the descriptions of some of the processes in the earlier edition have been removed. The principle governing these removals has been to omit those processes whose value is too well known and have been so generally adopted that they can no longer be considered as novel; while others, again, have not proved so trustworthy as older ones, or have been superseded by more accurate methods of newer date. Assaying and volumetric processes have also to a great extent been omitted, partly because they do not come within the scope of the book, but more particularly because they are well provided with a special literature of their own. The space so gained has been to a great extent utilised for discussing methods of electrolytic separation as given in the standard work by Dr. Classen, of Aachen, on "Quantitative Chemical Analysis by Electrolysis," their application to individual separations being given under the heads of the different metals; while the apparatus required and general methods of manipulation form part of a special chapter, which, together with the illustrations, is reproduced from Dr. Classen's original work—but, unfortunately, not in the tongue of the original, a sort of "English as she is wrote" being preferred, as will be seen from the following extract:—"As it will appear below, for the performance of a quantitative determination or separation, a *quite definite* strength of current is not required; it always fluctuates within certain limits, so that in the majority of methods of determination several c.c. of detonating gas more or less per minute is not of importance. It is only thus possible for electrolytic analysis to be effected without further difficulties." The remainder of the extract, about nine pages, contains similar Anglo-Teutonic obscurities; after which a note by an electrician, Dr. Sloane, is given, criticising the description as insufficient, on account of the voltage of the current being neglected. This seems to be rather an odd way of rewarding Dr. Classen for his kindness in permitting the reproduction of his matter and illustrations in the present volume. A more practical method would have been to have presented it in a readable English form.

The chapter on cerium and the allied rare earthy metals has been considerably enlarged, as might be expected, this group of metals being the subject of some of the author's most interesting and successful lines of research, and it is in this part, and this only, that references to original publications and dates are systematically given, a circumstance which makes their absence elsewhere the more noticeable. Such omissions are much to be regretted, as they may in places make the book misleading to beginners, and irritating to those of larger knowledge. For instance, Dr. Lawrence Smith's excellent process for the determination of alkalies in silicates is described at length by reproducing the original paper, "as it appears to be almost unknown in England." This statement was not quite a proper one to make at the period of the first edition of this work, as the process was perfectly well known and used in London within twelve months of the time of the original publication in America, and the propriety is certainly not increased when it is produced twenty-three years later in a book said to be re-written. On page 37 a "recent note" by Professor Lawrence Smith is mentioned, that distinguished chemist having been dead for more than ten years, and in like manner, on page 252, Claudet's process for the extraction of silver from burnt pyrites is noticed as having proved a success after "nearly six months' experience at Widnes," a statement no doubt of historic interest, considering that the process has added millions of ounces of silver to the world's stock of that discredited metal, and that the patent covering it expired in 1889, but which seems out of place in a book whose main purpose is supposed to be the recording of new analytical processes and improvements in older ones. In these latter respects we are surprised at not finding a notice of Roth's process for separating iron without precipitation in the analysis of ferro-manganese and similar special iron alloys by the use of hydrochloric acid and ether, which seems to be one of the most notable advances in technical methods of analyses made of late years. The Eschka process for the assay of mercury ores has also been improved since the method described on page 257 was originally brought out.

We suppose that the index maker must be taken to be responsible for the mystification practised on the reader by the startling headline on page 433, "Employment of Cadmium in Cupellation," as it also appears in the index, but which turns out to be a description of the use of that metal as a substitute for silver in the parting assay of gold bullion.

Taken as a whole, the book is disappointing. The author's own contributions are of standard value, and must be mentioned with due respect and regard, but their effect is certainly diminished by the mass of ancient padding incrusting them.

## *BOOKS RECEIVED.*

*The Indian Engineer's Diary and Reference Book for* 1895. Calcutta and London: The *Indian Engineering* Offices. This is a quarto diary, four and three days on a page, interleaved with blotting paper. The reference part comprises an unusually large quantity of useful matter selected with a view to the requirements of engineers in or doing business with India. It also includes a valuable article on India as a field for industrial enterprise, which contains a great mass of statistical and other matter on industries and resources of India not easily otherwise obtainable.

*Notes on Concrete and Works in Concrete.* By John Newman, Assoc. M. Inst. C.E. Second edition. London: E. and F. N. Spon. 1894. The first edition of this book was published in 1887, and has proved very useful to those for whom it is intended, namely, those engaged on public works, but it has proved equally useful to any engineer called upon occasionally to use concrete for different purposes and under different conditions. During the past six or seven years great additions have been made to the literature of concrete and works in concrete, chiefly in papers read before engineering societies. These additions appear to have been carefully followed, and a digest judiciously incorporated in the new edition has increased its volume by a hundred pages, enabling it to retain its position of one of the most useful books on the subject. It would be improved, however, if it had a better index.

*Kitchen Boiler Explosions: Why They Occur and How to Prevent Their Occurrence.* A short treatise giving the results of practical experiments with red-hot boilers. By R. D. Munro, M.I.M.E. Price 3s. London: Charles Griffin and Co. 1895. In this brochure the author describes a series of experiments made with a form of kitchen boiler with water admitted under various conditions, imitating those which have been assumed to occur when kitchen boilers have exploded, the assumption being that empty boilers have been heated, the ice obstructions in the connected supply pipes melting and the water supply thus suddenly established. The whole of the author's experiments show that kitchen boilers explode as a result of the commonest cause, namely, too much pressure, and that the best preventer is a safety valve. Mr. Munro's experiments were carefully planned and made, and the results are confirmed by his experience as the chief engineer to the Scottish Boiler Insurance Company.

*Refuse Destructors, with Results up to the Present Time.* Second revised edition. By Charles Jones, M. Inst. C.E. With a paper on *The Utilisation of Town Refuse for Power Production.* By Thos. Tomlinson, A.M.I.C.E. 5s. London: Biggs and Co. 1894. Mr. Jones has so many years made this subject almost his own that his book must participate in the very general attention that is now being paid to it by municipal engineers by those who are looking to get at least the day load of an electric light station supplied with steam from the heat of town refuse destruction. Much greater hopes in this direction are sometimes indulged in than are warrantable, as shown by Mr. Jones and by the paper by Mr. T. W. Baker. which we recently published in our columns. Great advances are however, being made in the construction of destructor furnaces and in the conservation of the heat obtained, and Mr. Jones' book will be found valuable on the structural and particularly so on the statistical sides of the subject of refuse and its destruction.

## SIR JOSEPH C. LEE.

We regret to have to record the death of Sir Joseph Cocksey Lee, some time deputy chairman of the board of directors of the Ship Canal. For months his health has been failing, and we believe that he was last seen in Manchester on the occasion of her Majesty's visit to the canal in May. Since then he has travelled about visiting various health resorts, and at the time of his death on Monday, 17th inst., was staying at St. Leonards-on-Sea. Born in January, 1832, and educated at the Manchester Grammar School, Mr. Lee entered upon his business career in the house of which he subsequently became a partner. As a merchant and shipper he was always looked upon as an expert in all questions affecting tariffs, treaties of commerce, navigation, &c., and was frequently consulted by the Foreign-office. In 1881-82 Mr. Lee was appointed British delegate to the commission sitting at Paris relating to the Anglo-French treaty of commerce. It was in recognition of his eminent services and the unqualified success of his mission that he received the honour of knighthood in 1882.

Sir Joseph has all his life taken the keenest interest in Manchester enterprise, and as one of the originators and subsequently as chairman, without doubt contributed by his energy and business capacity to render the Royal Jubilee Exhibition the brilliant success it was. But it is in connection with the Ship Canal that Sir Joseph's name will ever be most remembered by Manchester. In 1884, as the representative of the Manchester Chamber of Commerce, he gave evidence in support of the Bill before the parliamentary committees, and joined the board of directors in the following year. In 1886 he was elected deputy-chairman of the company, a position which he continued to hold till June, 1893. Shortly after taking office, that unfortunate difference of opinion arose which subsequently led to the resignation of Mr. Daniel Adamson, the pioneer of the canal. As a matter of fact the dispute was almost a personal one between Sir Joseph and Mr. Adamson, and so keenly did the former feel at this crisis, that he actually tendered his resignation. Subsequently Mr. Adamson resigned, and Sir Joseph's policy was accepted by the board of directors.

It is now clear that whereas the obtaining of the Bill and the parliamentary fight owe much of their success to the dogged perseverance and tenacity of Mr. Adamson, the policy proposed by him for raising the capital must have resulted in failure. In fact it is doubtful whether any other man than Sir Joseph could have adjusted matters with the large financial houses of London at that time so satisfactorily and successfully. These long and difficult negotiations, and the great strain and anxiety following on the letting of the contracts were a most severe tax on Sir Joseph, and without doubt his death was hastened by his devotion to the duties of his office. Of the original directors of the company, we believe that only two now survive; the others, together with the first contractor, Mr. T. A. Walker, and the company's enthusiastic solicitor, Mr. W. J. Saxon, having fallen victims one by one to the cause of the great shipway. Sir Joseph Lee, the financial genius of the scheme, will ever be remembered for his successful efforts on behalf of the canal.

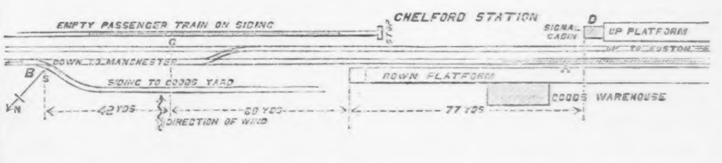
## THE CHELFORD RAILWAY ACCIDENT.

The frightful accident which occurred on Saturday evening last to the Manchester and London express is a most extraordinary affair in many ways. As most of our readers will have learned from the daily press, the 4.15 p.m. North-Western up express from Manchester to Birmingham and Euston was wrecked at Chelford, a country roadside station, 16½ miles south of Manchester, and about four miles north of Crewe.

The train was a heavy one, and consisted of two engines, No. 418 "Zygia" leading, and No. 520 "Express," one of Mr. Webb's patent compound type, behind were sixteen coaches made up in two portions, the forward half comprising certain Great Western stock being for Birmingham, and the rear portion for Euston. After leaving Stockport the road is almost level and very straight, so that a high speed was soon obtained, and reports vary between forty and fifty miles an hour as the estimated rate at the time of the accident.

The time allowed for this run to Crewe is only thirty-five minutes for a total distance of twenty-five miles, and this includes start and stop.

It must also be borne in mind that the great gale of Friday night was still raging, and, as a matter of fact, was blowing almost broadside on to the track at this point. The signals indicated a clear road, and it was already more than dusk when Chelford section was entered. Here shunting operations were in progress, and the "down" main line in the station was occupied by the rear and main portion of the "down" goods. Our representative has supplied us with a sketch plan of the station, and has to thank a member of the London and North-Western Manchester staff, for his courteous detailed account of the actual occurrence, as it appeared to the company's servants on duty at the time. It seems that the goods train was left standing at A, and that the engine and one or two leading trucks had been backed down the siding from the trailing points B to pick up a wagon in the yard. This empty truck—one of the company's ordinary 4½-ton wagons—with low sides had been shunted down to the main train at A, and the engine was again reversed and slowly steaming a second time into the same siding to set down, when the up express dashed past.



What actually took place is not quite clear, and pending the holding of the inquest and the Board of trade inquiry, it is not for us to theorise as to the cause of the catastrophe which followed. The official statement is, that this low-sided empty truck was not immediately coupled to its train, but was blown back by the force of the gale towards B, and that it collided with the trucks entering the siding, and being derailed, fouled the up main at the very moment that the passenger train came opposite the point B. That something of this kind did happen is probable from the injury sustained by the leading engine. The offside is completely battered, and the tender also has suffered.

It would seem as if the truck must have been thrown for a moment right across the express, for the footboards of an empty coach standing on the siding at C were smashed, while the coaches and engine nearer to the station were unhurt.

Apparently, however, the wagon must have been thrown back again from the six-foot by the standing wagons at A; for the front of the signal cabin at D has been carried away. The shock of this impact must have again thrown the first wagon towards the down metals, and possibly it was this, crushing in between the express up and the stationary trucks of the down goods, which caused the great damage to the central carriages of the train. Singularly enough the engines were not derailed immediately, but ran into the station before the pilot left the track. The train stopped in less than its own length, and the rear portion was practically unhurt. A wagon struck and carried away two of the iron pillars carrying the roof over the down platform; yet the station master and one or two passengers who happened to be standing on that side escaped injury.

No doubt the Board of Trade inquiry, opened on the 26th under Major Marindin, will clear up this and several other points. At the inquiry the station master said in reply to Major Marindin, after giving particulars of the shunting operations, "As soon as he saw the empty wagon, which was a high-sided North-Western one, come to a stand, he gave the brakesman a signal to go ahead. The driver with sixteen wagons drew ahead. Witness walked down to the points and gave the signalman a signal to pull over the points for the siding, so that the engine might knock more wagons back into the siding. He gave the brakesman a signal that the points were set, and he then called the driver back. The nearest wagons to witness were about seven or eight yards away. The brakesman uncoupled about six of the wagons from the engine. When the brakesman had called the driver back witness walked south along the six-foot to see that the wagons which had been detached were safe in the siding. As he was going back he observed the empty wagon which had previously been knocked down the main line running, on the move towards him. When he first saw it it was a yard or two short of fouling the crossings. He ran towards it with a view of stopping it, but found that he had not sufficient time to get to it before it fouled the crossing. He immediately turned round and waved a red light violently towards the engine of the up express, which was then approaching. He had heard it coming, and saw it as he waved the light. When he first waved the light he could see the tender of the up express about 80 or 100 yards away. He ran towards the express, and still kept waving his light till after the driver had passed, but before that six wagons that were being knocked back had struck the empty wagon and lifted the end up. He saw it plainly. The end of the empty wagon was lifted up, and the wagon was pushed round and across into the six-foot. It was thus foul of the up line, but not across it.

The result of the collision was that fourteen passengers were killed on the spot and a large number wounded.

## UNITED STATES THIRD CLASS TORPEDO BOAT.

We commence this week the publication of a series of engravings illustrating a third-class torpedo boat for the United States navy. So much has been said in this country about the theft of designs that these engravings will no doubt be regarded with considerable interest. We believe, however, that they have nothing in common with the abstracted plans. The torpedo boat in question has been designed as part of the equipment of the United States battleship Maine. We shall give a detailed description in future impressions.

Liverpool Engineering Society. — On Wednesday evening, December 19th, the President, Professor H. S. Hele-Shaw, M. Inst. C.E., presided over a numerously attended meeting of this Society at the Royal Institution, Colquitt-street, when Professor Oliver J. Lodge, D.Sc., F.R.S., read a paper entitled "The Second Law of Thermodynamics." The paper was extremely interesting, and was listened to with great attention, as well as the remarks of Professor Fitz-Gerald in the discussion which ensued.

The Yorkshire College Engineering Society.—At a recent meeting of the above Society, at which Mr. J. H. Wicksteed presided, a paper was read by Mr. Edward E. Matheson, Stud. Inst. C.E., upon "Gold Mining on the Witwatersrand in the Transvaal." The lecturer, who has recently spent some time amongst the various mines in South Africa, gave a graphic account of Johannesburg, describing how in six years it had become one of, if not the, mining centres of the world. It was described as 1000 miles from Cape Town and 5700ft. above the sea, and possessing a population of about 45,000 whites and blacks. This town in so short a time has become possessed of fine hotels, an installation of electric light and telephones, a stock exchange, a public press issuing its evening papers, and many other conveniences of an English town. The Rand was only proved to be a gold-bearing district in 1884, although its existence there had been known some years before. The geology of the Transvaal was described, showing how the gold reefs were formed. The "Blanket" reef, from which the gold was obtained, was about fifty miles long, striking from east to west, and dipping at an angle of 60 deg. from north to south, Johannesburg being a little north of its centre. The formation of this reef was quite different from that of any other in which gold was known to occur. When mining operations were first commenced it was not thought that the gold reef would hold out to any depth, but their doubt was dispelled by the "Great Bore Hole" which proved the existence of reefs at a depth of 2400ft. One of the most fascinating and wonderful features of the "Blanket" reef formation was the extraordinary regularity of the amount of gold found in it, there being an average of ½ oz. of gold per ton of material mined in all parts of the district. Some of the deep level mines were sunk to 1000ft. The mines numbered about sixty, each being the centre of a small town, all the hard work was done by the blacks or "boys," who received about 16s. besides food and lodging for the week. The skilled white workers earned from £5 to £7 per week. The mines had been developed in a marvellous manner owing to the discovery of large quantities of coal close by the mines. Mr. Matheson then described the construction of the shafts, the mining of the reef, and the various processes connected with the extraction of the precious metal. At present, he said, only 85 to 90 per cent. of the total gold in the reef was secured, the remainder being entirely lost.

## THE MEIGS ELEVATED RAILWAY SYSTEM.

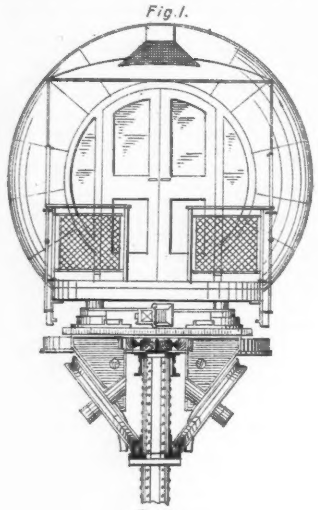
(*By our American Correspondent.*)

THE type of elevated railways invented and patented some years ago by Captain J. V. Meigs, of Boston, Mass., U.S.A., and which has come before the notice of the public from time to time, seems to be at last in a fair way of being put into actual execution, as it has been adopted for the new rapid transit system of Boston by a Bill passed during the summer of this year.

Since the time when the need of rapid transit for cities became apparent, inventors have turned their attention to elevated railways, and this has been more especially the case since the success of the first railways of this kind in New York. These inventions, however, have not, as a rule, met with much success; and the elevated railways as now constructed in New York, Brooklyn, Chicago, and other cities, are generally on the broad principle of a railway, with the ordinary form and construction of track or permanent way elevated on a continuous iron viaduct, with different kinds of supports. Such railways, although they are operated successfully and are a great convenience—in fact, New Yorkers especially would be lost without them—are yet open to a number of objections; one of the most serious of which is the annoyance to comfort and injury to property by the obstruction which the railway offers to light and air. The tracks, with closely spaced timbers, heavy guard timbers, and plank walks for the workmen, overshadow the streets and darken the houses and stores. This is particularly the case in narrow streets, and at places where stations, yards or additional tracks add to the obstruction offered by the main tracks.

Capt. Meigs, in designing his type of railway—which by the way is claimed to be adaptable for ordinary as well as city railways—took the above and other objections into account and endeavoured to avoid them. Having perfected his plans and protected his inventions by patents, he commenced negotiations for the right to construct a line to connect the adjacent cities of Boston and Cambridge, but met with opposition from the property owners and portagers—who wanted the railway but not on their own streets—and had the uphill work of introducing something novel and without precedent. Similar opposition was encountered in the Legislature, and it was only in 1884, after five years' fighting and reasoning, that the inventor secured the passage of an Act authorising the incorporation of the Meigs Elevated Railway Co. Having got his charter the inventor tried to start his line, but property-owners refused to give their consent for a road in front of their property, the aldermen declined to grant a location, and quasi-scientific people writing in the papers prejudiced popular opinion against the feasibility of the system. Capt. Meigs then decided to prove the practicability of his system, and secured a site in Cambridge for an experimental line about a quarter of a mile long, with sharp curves, heavy grades, and sudden changes of grades and curves. Different styles of construction for structure were also tried. A factory building adjacent was required, machinery put in, and a complete and full-sized locomotive, tender, and car built, complete in every detail. The first train was run in May, 1885. Some alterations were made in the engine later, and in 1886 the Board of Railroad Commissioners was requested to appoint an engineer—as required by the charter—to investigate, test, and report upon the system. The result was that after a prolonged examination and severe tests of the strength of the structure and the safety of operation of the trains, Gen. Stark, the engineer, made a very favourable report.

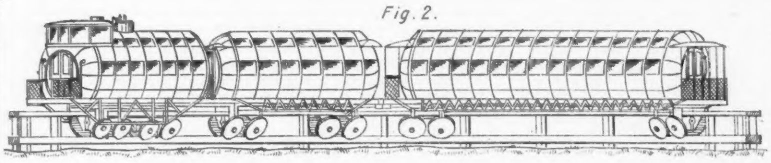
Fig. 1.



Still the city could not come to a decision as to the much-needed rapid transit system, and numerous projects for elevated and underground railways have been submitted from time to time. In July, 1894, however, the State Legislature passed a Bill incorporating the Boston Elevated Railway Company, which Bill has been approved by public vote of the city. The law of 1884 provided that the railways should not be built after the manner of the New York elevated railways, but according to the Meigs inventions. The new Bill does not so definitely specify the Meigs system, but prohibits structures similar to those of the New York roads. The Bill makes the company subject to all laws respecting railway corporations, provides for payment for land damages, and requires some return to the public for the franchise. In regard to the former Bill, it may be noted that the Railway Act provides only for gauges of 4ft. 8½in. and 3ft.; and the Bill had to make the Meigs Company exempt from that clause, as otherwise the railway commissioners could not grant a location, the widest part of the Meigs' track being only 22in. Charles A. Whittier is president of the company; Joe V. Meigs, chief engineer; and Herman Haupt, consulting engineer.

The structure consists of a single row of posts or columns—Fig. 1—carrying a single line of girders. For country lines wood may be used; but for city lines of course only steel or iron are used. The columns are 18in. by 12⅞in. in section, built up of two channel irons and two plates. The interior is filled with concrete, the top of which is covered by a plate, upon which rests the friction bearing forming the support for the end of the top chord of the girder; the weight being thus carried by the concrete mass. The longer dimension of the column section is parallel with the line of way. The columns will be normally 24ft. 4in. long, set 6ft. in the ground on a foundation of concrete or piling, and giving 14ft. clear headway under the girders. The columns will be 13½ft. to 45½ft. apart, centre to centre. The girders will be 12ft. to 44ft. long, according to location; they will be of the Warren or lattice girder type, 46in. deep, the single panels of Warren girders being 4ft. long. The top and bottom chords, or booms, of the girder are each composed of a vertical plate and two angle irons. On the top chord are two angle irons placed to receive the longitudinal timber of the top rail, and the angle irons of the lower chord carry the longitudinal timbers for the lower rails, the trucks, or "bogies," straddling the girder.

Fig. 2.



In an ordinary elevated railway the track is about 8ft. wide at least; that is over the sleepers, and not including the usual extra width of the footway for trackmen. There is therefore this continuous width—for the sleepers are very close together—of obstruction to light and air. Besides this, the track is carried by two lattice or plate-deck girders 4ft. to 5ft. deep, and about 5ft. apart. With two tracks laid side by side, and with the further obstruction of cross-girders over the columns, and of sleepers at crossover roads, &c., some idea of the general effect upon a narrow street may be imagined. In the line at Hoboken, N.J., an attempt has been made to reduce this obstruction by laying each rail upon blocks of wood resting upon brackets riveted between two deep channel irons, the sleepers being thus eliminated, and the channels forming inside and outside guards to each rail.

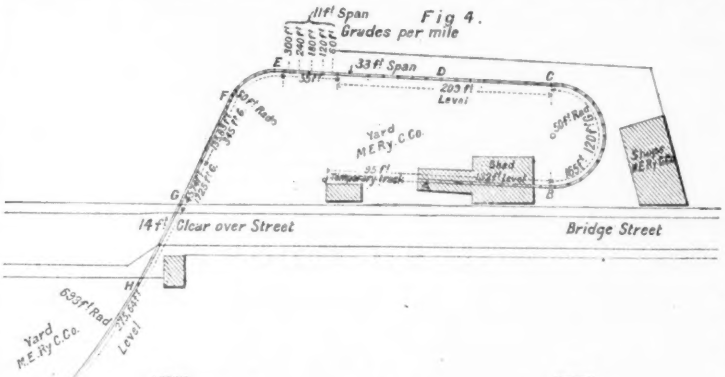


Fig 3.

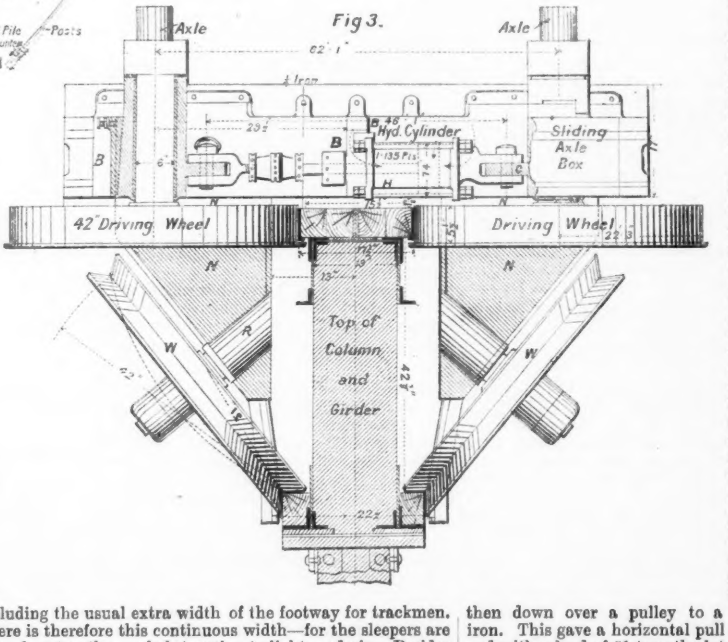


In the Meigs system, however, there is but one line of girders, Fig. 2, to each track, the depth being about 4ft. The maximum width for each track is 17½in. over the rails on the top chord, and 22½in. over these on the lower chord. These lower rails are wooden longitudinals, with the top outer corner faced with angle irons fitting the V shaped rims or treads of the car wheels. The longitudinals may be bevelled and carry flange rails for wheels with grooved treads. The upper rails are either wooden longitudinals faced with iron for the horizontal balance and driving wheels, or may be flange rails laid on their sides. In this way the cars have a depth of 48in. to resist derailment, instead of about 1in. of a wheel flange, as in the ordinary system. The switching or shunting will be done by a pivoted girder. The inspection may, perhaps, be somewhat difficult, but maintenance repairs can be effected from a wagon with a platform adjustable at any desired height, such as is used by electric railway companies for repairs to the overhead wires.

A feature of the Meigs system, which is equally as important as the single-girder track, is the construction of the car trucks, "bogies," Figs. 3 and 7, which straddle the girder. Each truck has four loose carrying-wheels with grooved treads, running on the lower chord of the girder, each wheel being carried on a short independent axle and being inclined outward from the rail at an angle of 45 deg. This at first seems a rather unstable arrangement, but theoretical investigation and practical experiments have shown, it is said, that it is not objectionable. In the unlikely event of a wheel, or all four wheels, breaking or coming off or part of one of the rails being removed, the car truck would merely drop a few inches until it rested upon the girder, and the truck frame, extending down on each side of the girder, would, in any event, prevent the truck from falling off the track, or the car from overturning. Each truck has also a pair of horizontal balance or guide-wheels, placed between the carrying wheels and bearing on opposite sides of the upper rail. These wheels are set up to the rail by springs, and have each a flange on the lower edge, which runs under the rail and so prevents the truck from lifting.

The experimental track—Figs. 4 and 6—at Cambridge was built purposely with severe conditions of grade and curvature in order to demonstrate the capabilities of the system. It is composed as follows, the letters being marked on the accompanying plan—Fig. 4:—

O to A, 95ft.; cheap form of wooden track for yard use, with no iron rails. A to B, 132ft.; heavier wooden structure, with iron rails on upper and lower tracks; straight and level. B to C, 165ft.; similar construction, but on rather more than half a circle of 50ft. radius and a grade of 120ft. per mile. This curve is a very severe test of the engine, which, however, passes it very easily. C to E, 264ft.; wooden structure, straight and level, including a wooden truss girder of 33ft. span; followed by five wooden spans of 11ft. each, all on different grades changing abruptly, the grades being 60ft., 120ft., 180ft., 240ft., and 300ft. per mile. E to G, 181ft.; wooden structure from E to F, on a curve of 50ft. radius, nearly 80 degrees, with a grade of 345ft. per mile; then an iron structure with grades of 345ft. and 172ft. per mile. G to I, 276ft.; from G to H are two iron girders of 46ft. span, such as will be used for city railways. These cross the street, and are followed by an iron structure with short straight sections making a curve of about 700ft. radius. The total length is about 1114ft.

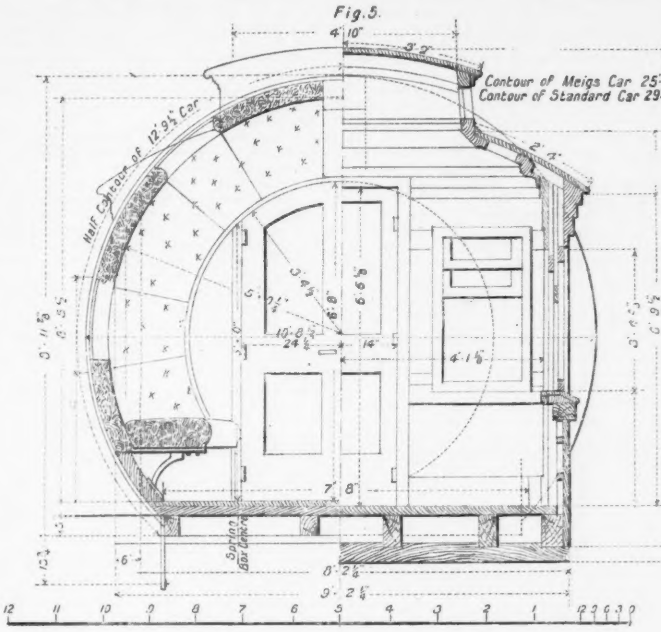
The iron girders, 46ft. long, are lattice girders built up of angles and bars, with angle iron diagonals under the bottom chord, and this was the character of the structure tested by General Stark for the railway commissioners. With a weight of 30 tons—cylindrical tanks filled with water—suspended by a chain from the middle of the girder, equal to a distributed load of 60 tons, the deflection was only $\frac{7}{16}$in., and there was no permanent set. To test the lateral strength of the structure in the event of a heavy gale blowing squarely against the side of a train, a cable was attached to a timber on one side of the girder, and carried horizontally to the top of an A frame, and then down over a pulley to a platform loaded with pig iron. This gave a horizontal pull on the middle of the girder, and with a load of 5¼ tons the lateral deflection at the middle was ⅜in., the movement causing the columns supporting the girder to bend ½in. at their tops. On the removal of the load the girder and columns returned to their normal positions. This would be the effect of a wind blowing at 33 lbs. per square foot against the train, equivalent to a hurricane of over 90 miles per hour.

The railway structure, the saddle truck, and the arrangement of the driving gear of the locomotive are the essential parts of the Meigs system, but in the train built a number of minor improvements in detail were introduced as noted later on. The bodies of the cars, Figs. 5 and 7, are of cylindrical form, with partially rounded ends, and the engine and tender are closed in with housings of the same form.

The locomotive is carried on two four-wheel trucks, each provided with a pair of horizontal balancing wheels, exactly the same as the car trucks. Between the two trucks or bogies is placed the pair of horizontal driving-wheels which grip the upper rail. To all intents and purposes the engine consists of a platform or flat car, upon which are mounted a boiler and a pair of horizontal stationary engines, so that the sizes of boiler and fire-box are not limited by the frames as in ordinary locomotives. The boiler is of steel, 5ft. in diameter, and 15ft. long, with 208 tubes, 2in. diameter and 7ft. long. The centre line is 5ft. 1in. above the floor. The fire-box is 54½in. long, and 54in. and 55in. wide, with the crown sheet inclined downward toward the rear end, so as to keep it covered with water on grades as steep as 800ft. to the mile. Anthracite coal is used for fuel.

A peculiar feature of the engine, which is especially striking when seen at work, is that there are no connecting-rods, but on the under side of each crosshead is a sliding box with a vertical pin, which is fitted into a horizontal crank-arm on top of the 6in. vertical axle the driving-wheel. The cylinders are 16in. by 22in., placed at the smoke-box end, and having the valve chests on top, in accordance with standard American practice. The cylinders are horizontal, and 61in. apart between centre lines. The piston-rods carry large crossheads, each travelling on two heavy bar guides, and driving the wheels in the manner above described, the arrangement being that known as the "slotted yoke" connection. The link motion valve gear is used, the excentrics and links being horizontal and under the crank arms, operating the valve rod through the intervention of bell cranks. The driving-wheels are 44½in. diameter, with cylindrical tires 6½in. wide, and flanges on the lower edge of the tires. At first it was not thought necessary to couple the drivers, but in practice it was found to be desirable in order to ensure steadiness of the engine. Gearing has been adopted for this purpose, there being a gear wheel on each driving axle and two intermediate gear wheels. The adhesion is obtained by hydraulic power, Fig. 3, each axle-box being carried in horizontal slides and attached to the piston-rod of an hydraulic cylinder, so that the pressure can be regulated according to the loads and the grades. The present engine can stop and start at will on a grade of 345ft. per mile, and sufficient pressure can be applied to crush the track itself. This pressure can be used as braking power. The blast pipe has a large nozzle, the exhaust being unobstructed.

Fig. 5.



The cylindrical form of the housing gives ample room inside for communication between the engine and tender and for attention to the machinery. At the front of the locomotive is the cab, being a raised platform enclosed, fitted with windows and covered by a monitor roof. From this station the engineman has a clear view of the track, and has ready to hand all the levers for controlling the engine, brakes, &c. The fireman's station is at the rear end, but, as before mentioned, there is convenient communication. An objection that may be made to the position of the cab is that it is liable to injury in case of any slight collision. It sometimes though rarely happens on elevated railways that in foggy weather a train will run into another which has been slow in getting away from a station. Owing to the low speed at such times there is usually very little damage done, except to the rear platform of the car, but the driver of a Meigs engine would stand a fair chance of being injured, or at least cut by broken glass, as he would be right in front of the engine instead of being protected by the length of the boiler. This objection might be eliminated by extending the front platform and building it heavily. The cab is reached by steps, and is accessible from doors in the front of the housing—opening out on the front platform—or from the interior of the engine.

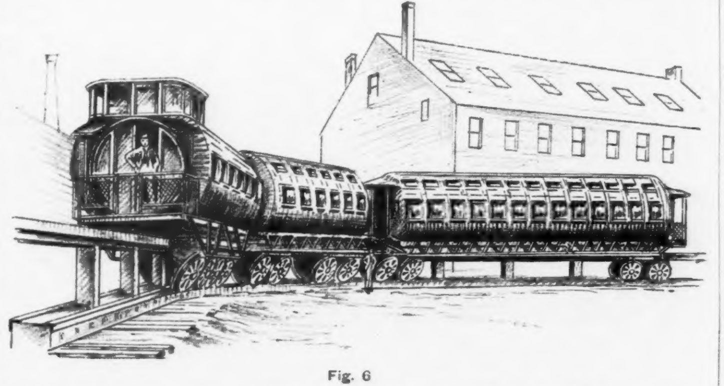


Fig. 6

The engine is 29ft. 3in. long over all and 7ft. 6in. wide, weighing 30 tons. Next to the engine is the tender, carried on two trucks of the type already described, and having a cylindrical housing. It contains two cylindrical water tanks, with a capacity of 1800 gallons each, and there is ample coal space. The size of the tender is 25ft. 9in. long and 7ft. 6in. wide across the floor, and its weight is 14 tons. On the experimental train there is no brake except the controllable grip of the driving wheels, which is amply sufficient as far as power goes, but for actual operation of trains some form of continuous automatic brake would be used, and it has been proposed to use an hydraulic brake acting on the balance wheels, and causing them to grip the upper rail.

The underframing of the passenger cars consists of a pair of Warren girders about 18in. deep, making a strong construction to resist collisions. The body is of the cylindrical form, with rounded end corners, and has end doors and platforms. The body framing consists of light ribs of T iron, bent to a circle 10ft. 8½in. diameter, the spaces between being filled in by panels of galvanised iron, lined with asbestos inside and sheathed with wood on the outside. The car is 51ft. 2in. long over all, 7ft. 6in. wide on the floor, and weighs 17 tons. The floor is of ⅝in. floor boards, laid diagonally, and nailed to an under floor of 1½in. planks carried by floor beams of 5in. channel irons. The car is very roomy and comfortable. Along each side is a row of seats as in street cars, but instead of the entire middle portion of the floor being left unoccupied, there is a single row of seats with the backs alternated, so that passengers face to right and left alternately. With this arrangement the car has seating capacity for eighty-four passengers, as compared with forty-eight on the cars of the New York and other elevated railways. The windows have hinges instead of sliding sashes, and by a device invented by Capt. Meigs, the window can be opened at either end, so that in whichever direction the car is moving the "rear" end of the window can be swung out, hinging at the "front" end, so that the passengers can have fresh air and at the same time exclude dust and cinders. The upholstering is carried right to the window space, and the sash fits against it, so that there is no draught when the windows are closed. A row of smaller windows is placed on each side of the upper portion of the car, being provided with curtains to shut out the sun. Ventilation is provided by an air-pipe, or trunk, along the top of the ceiling, having trumpet-mouth ends outside the car, and having valves in the lower part to regulate the draught. Semicircular pipes against the sides have openings under the seats and connect with the longitudinal trunk, so that as the car moves the interior air is drawn out from the top and bottom. Each end of the car has double swing doors opening on to an end platform, with the usual arrangement of roof and railings. The platform gates, however, instead of opening by swinging back on the platform, as on other cars—which is very troublesome when the cars are crowded—are made to slide vertically downward, being raised again by cords passed over a drum operated by springs. The upholstering is in red plush for the seats and old-gold plush for the sides and ends. Steam-heating pipes may be carried along under the seats, and lamps hung from the roof in the usual way.

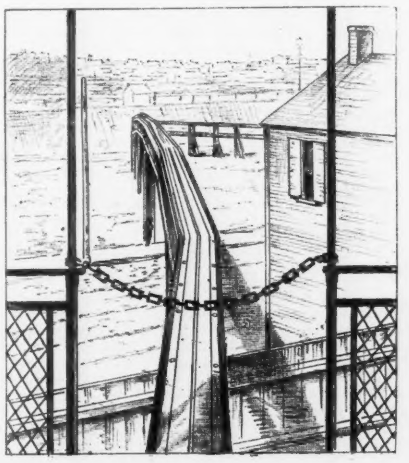

Fig. 7

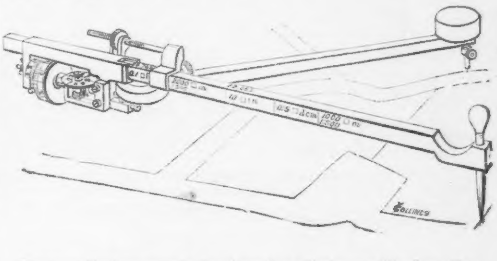
The car body is not attached to the truck by means of a centre-plate and king-pin or pivot, as in the ordinary type of car, with which arrangement it not unfrequently happens that in case of accident the car body is knocked off the trucks. Instead of this, another of Capt. Meigs' inventions is used. Attached to the under frame of the car, over the truck frame, are four hollow vertical cylinders, with the bottom diameter reduced by an interior flange. These carry a turntable which rests on two semicircular slides or bearings on the truck frame. On the truck frame are four vertical hollow cylinders, with the exterior diameter longer at the top. The inner flanges of the upper cylinders engage below the outer flanges of the lower cylinders, so that it is impossible for the car body to lift off the trucks. Coiled springs are placed in the cylinders. A rim on the turntable also engages the curved truck bearings. The usual form of king bolt connection is used for pivoting the truck or "bogie." The car couplings are an adaptation of the Miller automatic link coupling, as now almost universally used on the best passenger cars, but are controlled by the engineman by means of hydraulic connections.

In regard to speed, the existing line is too short for any high speeds, but the 50ft. curve has been easily taken at a speed of fifteen miles per hour on the down grade. Elevated railways as now built are but little hampered by snow, as it does not lie deep and is easily disposed of, and in Mr. Meigs' system there is even less space for it to lodge.

## COMPENSATING PLANIMETER.

The improvement in the planimeter illustrated by the accompanying engravings is the joint invention of the patentees, Mr. W. F. Stanley, of Great Turnstile, and Dr. A. Amsler, son of the inventor of the well-known instrument bearing his name. It consists in making the instrument adjustable to the shrunk scale of a printed ordnance map, or other plan which has shrunk in mounting, by providing means for making a correction equal to the difference between the standard and the shrunk scale of the map. The correction for shrinkage is made by means of a short scale upon the top of the planimeter divided to hundredths, which reads with a vernier to thousandths of the length of the tracing arm. The percentage of shrinkage is found by measuring the scale of the map by a true scale, and setting off double the percentage difference upon the vernier scale from zero. The planimeter adjusted in this way measures the area on the shrunk map, if care be taken in following the outline of the plan or map to be computed with the tracing point.

The following explanatory calculations have been furnished by Dr. A. Amsler:—Theory. Let A denote the area of a square, the side of which has the length $a$ expressed in any unit. Then $A = a^2$.



Suppose that square to be shrunk so that one side has the length $a - \alpha$, and the other side the length $a - \beta$. The area A′ of the shrunk square will then be expressed by

$$A' = (a-\alpha)(a-\beta) = a^2 - a(\alpha+\beta) + \alpha\beta = a^2 \left\{ 1 - \frac{\alpha+\beta}{a} + \frac{\alpha\beta}{a^2} \right\}$$

$\alpha$ and $\beta$ being small quantities compared with $a$, the term $\frac{\alpha\beta}{a^2}$ is of the second order in comparison with unity, and may be neglected, so that

$$A' = a^2 \left(1 - \frac{\alpha+\beta}{a}\right) = A\left(1 - \frac{\alpha+\beta}{a}\right) \quad . \quad (1)$$

As is well known, the area P of any diagram measured by means of a planimeter is equal to $P = r\,y$, $r$ denoting the length of the tracing arm, and $y$ the reading of the roller. The area of the same diagram, measured by means of the same planimeter, but with the tracing arm adjusted to the reduced length, $r\left(1 - \frac{\alpha+\beta}{a}\right)$ would be expressed by $P = r\left(1 - \frac{\alpha+\beta}{a}\right) y'$, $y'$ denoting the new reading.

Let now the diagram to which P refers be identical with the shrunk square, then $P = A'$ and $A' = r\left(1 - \frac{\alpha+\beta}{a}\right) y' = A\left(1 - \frac{\alpha+\beta}{a}\right)$

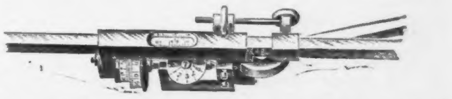
$$A = r\,y' \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

This formula shows that the true area A is determined from the shrunk square by setting the tracing arm to the length $r\left(1 - \frac{\alpha+\beta}{a}\right)$ exactly in the same way as by setting the tracing arm to the length $r$ and measuring on the true square. The same reasoning holds good for any shape of diagram.

If $\alpha$ and $\beta$ are expressed in percentage of $a$ then

$$r\left(1 - \frac{\alpha+\beta}{a}\right) = r\left(1 - \frac{\alpha+\beta}{100}\right) = r - \frac{r(\alpha+\beta)}{100}$$

The illustration *above* shows the new planimeter is identical with the usual form with movable arm. The figure *below* shows the top face of the sliding bar with two short graduations and two verniers each corresponding to one mark on the side faces of the bar.



The use of the planimeter on shrunk plans is very simple. Suppose, for example, a 6in. to the mile plan. Measure on the shrunk plan by means of a true scale the length of 100 divisions of the scale printed at the bottom of the plan. Say, for example, that length may be 98·6 on the true scale, so that the deficiency is 1·4; multiply the deficiency by 2 — 2 × 1·4 = 2·8; then adjust the zero point of the vernier to 2·8 of the graduation on the top of the bar. This vernier and graduation corresponds to the mark.

0·5 ac. 10′ = 1 mile.
2 ac. 5′ = 1 mile.
50 ac. 12″ = 1 mile.
200 ac. 6″ = 1 mile.

The reading of the roller multiplied by 200 will then be the true area.

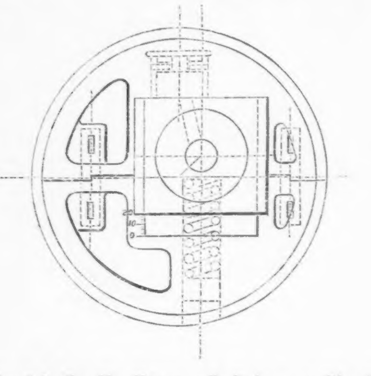
If a net of squares is printed on the map and it ha shrunk at different rates in the horizontal and vertical directions—say, for example, at such a rate that the deficiency in one direction is 1·4 and in the other direction 1·6—then add the two deficiencies 1·4 + 1·6 = 3 0 and adjust the vernier to 3 0 of the graduations on the top of the bar.

## LETTERS TO THE EDITOR.

(*Continued from page* 570)

### GOVERNING ELECTRIC LIGHT ENGINES.

Sir,—Mr. C. L. R. E. Menges in his last letter guesses quite correctly that my regulator must be inserted in a shunt, which in fact is really the case. From the main is shunted off one cable for all the lamps necessary for engine-room and stokehold, and this cable goes round the coil of the solenoid and regulates the voltage in the mains. What Mr. Menges puts down as the correct principle necessary to govern the voltage is realised by my patent governor. Let, for instance, 20-horse power be the total power required for feeding all the lamps, Mr. Joy's fluid pressure excentric is so placed that when at its maximum stroke the engines will give 20-horse power. Should now, for instance, half the number of lamps be turned out, we only require, say, about 10-horse power, and the governor will place the excentric disc in a position to admit steam to produce only 10-horse power, which means to say, to each number of lamps corresponds a certain position of excentric disc, and to place the disc in this position is the function of the governor.



This "variator," as Mr. Menges calls it, is so sensitive that it does not allow the excentric to rest in any other position except the one which corresponds to the prescribed normal voltage.

In my last letter my name was spelled—as usually foreign names are—entirely wrong, and I hope the compositor will be more successful this time.

F. Kodolitsch,
Lloyd Arsenal, Trieste.

Trieste, December 20th.

[Usually foreign names are almost, if not altogether, illegible as written. Compositors are not endowed with superhuman power, although there is reason to believe that they possess something closely akin to it.—Ed. E.]

### LOCOMOTIVES AND TRAINS.

Sir,—It may not be out of place if I say a few words concerning what you have not badly called a "sulky" engine. I have had my own turn at engine driving and firing, and know practically what I am writing about. The locomotive boiler is a very delicate affair, and requires much skill to get the best result out of it. It is used on land as a stationary boiler, and at sea. For all three purposes the working conditions are different. I shall speak only of its use on railways. On this point the amateur is hopelessly at sea, he can know nothing about it. I propose to enlighten some of your correspondents. I daresay many of them will take what a practical man has to say in good part.

The first thing to consider is the work the boiler has to do. Now the demand for steam continuously varies all along most roads. There are, of course, stretches like that from Paddington to Swindon, on which firing is child's play when you know how; but on most lines the demand for steam varies continuously, but the good fireman will keep the hand of the pressure gauge steady as a rock. This he manages by the use of his fire door, his ash-pan damper, and his injectors. Every engine has its peculiarities—why it should be so I cannot attempt to explain—and only the driver and fireman who understand those peculiarities can get the best result out of an engine. The consequence is that when a strange crew are put on an engine, even of the same class to which they are used, the result will be bad in all probability. Thus, for example, all locomotives run with the gauges showing a full glass. I have known an attempt made to use long glasses, but it came to nothing; only experience can tell the driver or fireman whether too much water is going in. Skilled men driving an engine to which they are accustomed could, I believe, get on without a glass at all. My practice was to run with one injector always on, and it is the usual practice. This did not throw quite feed enough. The rest is made up by using the other injector almost by instinct. The engine is running with a full glass of water, so high as to be out of sight; steam is shut off and the water instantly drops. There may not be half an inch in the glass, but when steam goes on again up goes the water. Now, Sir, some engines carry their water better than others; but a man on a strange engine cannot tell where he is, and very often his feeding becomes unequal, and his steam goes flying up and down.

Next as to the fire. A man gets away with his fire out of condition; there are holes in it, or the fire is too green—down goes the steam. If the fire is of the right sort and the driver not impatient, and they have confidence, all will come right by-and-bye, the driver sparing the engine all he can; but if the fireman takes to the dart and pulls his fire about, he is done. One thing must never be forgotten: If a locomotive can once get to blowing-off pressure, she can be kept there with much ease; but once let the steam get down, and it passes the art of man to get it up again. The reason is that the blast is much less effective, and that a much larger quantity of low-pressure steam is used—because the steam is used less economically.

In certain states of the weather locomotives often sulk. This is specially true of damp, muggy weather. There is no life in the air, and slipping takes place; this tears the fire to pieces and ruins it. There is a great deal in the shape of a fire, and shape is spoiled by rude variations in the force of the blast. One engine will steam better with a fire heaped up in the middle, and thin at the sides; another likes a hollow top fire—just the reverse. This depends in a measure on the shape and condition of the brick arch.

There is nothing so likely to beat a driver and fireman as a change in coal. I can call to mind how I came many years ago to grief in this way. I was firing an engine south of Stafford, and we had nothing but a bituminous coal with lots of flame and smoke in it. It was a thin fire or nothing. Fire heavy, and the coal all ran together and air could not get through. When you knew the coal it was grand. Well, one day, instead of changing engines at Stafford, we had to take the train on. We had to take about a ton of coal. In those days we did not think very much of the loss of a couple of minutes coaling. Well, this coal was not like any either I or my driver had used, and in a very short time the pressure began to fall. We got down to about ten miles an hour. Then I got desperate, and I began to fill the fire-box, and then the pressure began to rise. After that I had no trouble. The new coal wanted a very thick fire, for it was dry—not much flame in it. A man will sometimes have to take an engine at short notice, with coal out of another district, and then trouble may be expected.

But apart from sulky engines, just think of the difference between pulling a dozen coaches on a fine, bright, calm day, and doing the same thing in a hurricane of rain and wind. Instead of complaining that locomotives do not keep time, the wonder is that they are so punctual. As to big engines, there cannot be two opinions. The difference between feeling an engine under your feet that can run away with a train and one which is loaded within an inch of its life must be felt; it cannot be described. It is like driving a worn-out old horse scarcely able to drag his tail after him, and sitting behind a fine horse in the pride of life.

The proper driving of a modern locomotive with a heavy train behind it, not once or twice but all the year round, demands a display of skill and experience which are not understood by the public. The driving of metropolitan trains stopping every couple of miles or less is nothing to the running of express trains, as fast as they can be got to go. Your readers, Sir, I can assure them, may believe me when I say that every locomotive has its whims and its crotchets, its good days and its bad days. This is not a driver's superstition, it is a fact. No doubt it admits of explanation, but it is hard to explain. Why will one of two engines, so much alike that all the parts are interchangable, always burn a couple of pounds a mile more than the other, no matter how the firemen and drivers are changed? I daresay there is a simple explanation, but I do not know what it is. Things do turn up now and then that almost make one think that locomotives are alive and can reason, but with these I shall not worry you. If I can persuade your readers that there are more things in locomotive engine-driving than appear on the surface, and can be seen by any railway passenger who looks at an engine, I shall be content. I could say a good deal about pilots. There is a time to take them and one to let them alone, but I must not begin about them or many other things, or I shall not know when to stop.

Old Driver.

Warrington, December 17th.

Sir,—Whatever its practical value, Mr. C. Rous-Marten's article, rather whimsically entitled "Eighty-four Miles an Hour," is by far the most interesting contribution to the subject of railway speeds I have ever seen, and it will, as he says, dissipate a great many wild ideas hitherto entertained and believed. There used to be a tradition or legend of 12 miles in eight minutes having been done on the Great Northern, which, however could not be authenticated for fear of getting the engine driver into trouble. Mr. Rous-Marten rather leads us to infer that the rate of 84·1 miles an hour very closely approaches the limit of speed even of locomotives of the 8ft. single type, owing to back pressure, but I think this point requires some further elucidation.

Other things being equal, the back pressure would mainly appear to depend on the piston speed of the engine, and there is a wide discrepancy between the piston speeds of, say, the 6ft. 6in. coupled Caledonian engines and that of the 8ft. 1in. Great Northern singles.

Assuming for the sake of argument that eighty miles an hour is the limit of the former, the piston speed is something like 1625ft. per minute, while that of the latter is only about 1250ft. per minute when running eighty-four miles an hour. I should therefore think the limit of speed of the 8ft. single engine would, other things being equal, be that represented by a piston speed equal to that of the coupled engine, and this seems to be 101 miles an hour. Whether there is anything in this or not, nothing is more surprising than the closeness with which the coupled 6ft. 6in. engines approach the speed of the 7ft. 6in. and 8ft. 1in. engines.

It would be interesting to know from "C. R. M." what is the highest speed attained on the level with an average load, and also what is the best time done in ascending banks like Shap and Elvenfoot. I am under the impression that, going north, the latter—ten miles—has not been done in less than fourteen minutes. I hope the author will shortly give us the further particulars of the runs he briefly mentions.

Your correspondent "J. G." complains of the weight of modern engines in comparison to their boiler capacity, but he may be quite sure the weight would be done away with if that were possible. The increase of weight is due to greater boiler capacity combined with increasing pressure, rendering everything heavier. Some of this extra weight would be required for adhesion in any case. It appears to me the alterations he suggests would mean a large further increase of weight.

Is not the question of very large engines really a question of policy on the part of locomotive superintendents? If all the London and North-Western Railway trains were sixteen to eighteen coaches then it would be advisable to build engines to handle them; but they are not, and, *pace* the opinions of some correspondents, I say the modern engine is still quite equal to its work; indeed, trains are often over-engined, and it is no unusual thing to travel 100 miles with a white feather all the way.

Isolated or exceptional circumstances are nothing to go by, and the best locomotive is and always will be the best compromise between the special conditions to be met. For my part, the more I see of a locomotive the more I admire its perfection and the ability of the men who designed it.

R. C. Dowie.

December 19th.

Sir,—I owe an apology to you and your correspondents for my statement that the large engine was taken on to assist the small one in the case of the train in the Northallerton smash. I was misled by a condensed report of the Board of Trade inquiry in *The Scotsman*, which the North-Eastern Railway people tell me is wrong, and that 1622 was making steam badly—a failure which may occur at any moment to any engine from many causes. For instance, the first portion of an express out of Edinburgh was stuck for twenty-five minutes near Berwick the other night because a "Tennant" engine could not make nearly enough steam. I remember the words of the driver of 1622 were that the brake pump "was sticking," and he was short of steam.

I have travelled a good many hundreds of miles on different locomotives, and I find the new large North-Eastern engines are very good steamers indeed. For instance, the other day I rode on 1619—the only compound of the class—which weighs 94 tons, from Newcastle to Edinburgh in a tremendous gale of wind from the west, which the Meteorological Office said had a velocity of forty-five miles an hour, with gusts up to between fifty and sixty miles an hour and driving rain; the small lumps of coal were flying off the tender. We had eleven E.C.J.S. and one N.E.R.T.P.O. = twelve. We left Newcastle eight minutes late, and only lost three minutes till within three miles of Edinburgh, when we were stopped twice at the bottom of the steep bank into Waverley, arriving nineteen minutes late. The whole 124 miles the gauge remained at 200 lb. except on three or four occasions when it fell to 190 lb., but never lower—and then only for a minute or less. Considering that the train was the "Flying Scotsman," the gale, and a consequently prolonged stop at Berwick because our water was very low, and the perfect steadiness of the gauge at 200 lb., it can hardly be said that 1619 is not worth her weight.

Norman D. Macdonald.

Edinburgh, December 24th.

### THEORY OF THE STEAM ENGINE.

Sir,—Referring to the first paragraph of Mr. Cross's letter in your last issue, it is obvious that Mr. Cherry referred to cases in which inventors have claimed for their engines extreme efficiency (usually expressed in terms of a wonderfully small coal consumption per indicated horse-power), an efficiency far exceeding that which, according to Carnot's theorem, is even theoretically possible. Under such circumstances, Mr. Cherry would surely be justified in applying the laws of thermodynamics, and pointing out to interested persons the fallacy of these claims; also in stating that any practical tests which apparently proved the alleged efficiency must necessarily be unreliable. It is well known that such cases exist both in the simple form, and complicated with false or misleading trials. I have myself carried out tests with properly designed brakes which have entirely shattered the records of previous so-called "tests" made with improper apparatus, and upon which the alleged efficiency had been based. Had these inventions been subjected to a theoretical investigation or analysis in their earliest stages, the expenditure of much money and time could have been prevented. I cannot therefore see that it requires a "vivid imagination" to connect similar cases with Carnot's theorem when the latter is applied in the manner indicated for the useful purpose of demonstrating the fallacy of the exaggerated claims set forth; and I certainly consider that scientific men are well employed when exposing the sophistry of ignorant or of designing persons.

W. A. Granger.

102, Brooke-road, N., December 24th.

Sir,—I am much amused at a writer of the calibre Mr. Maurice Cross has shown himself to be, suggesting that I should accept his mere baseless *ipse dixit* in preference to the teachings of my own close study and practical experience. I repeat that which I have already asserted, and surely I should know better than Mr. Cross that I have found Carnot's theorem of great practical value for the reasons and purposes among others which I have specified. I have already given Mr. Maurice Cross abundance of material for cogitation and reply. On his complete failure to furnish any logical reply, your readers will make their own comment. He continues to supply with every letter he writes additional matter for unfavourable criticism, but it would be superfluous for me to follow him further in his acrobatic arithmetic.

Henry Cherry.

21, Festing-road, Putney, S.W.,
December 22nd.

### LOCOMOTIVE CYLINDER CAPACITY.

Sir,—We notice a letter from "Nemo" in your present issue stating that the first Mersey Tunnel engines, built by Messrs. Beyer, Peacock, and Company, had the largest cylinder capacity of any British locomotive.

But we would call to mind the express locomotive James Toleman, which we built last year for the patentee, Mr. F. C. Winby, and which was illustrated and described by you in your issues April 28th, May 5th, and May 12th, 1893. This engine has two inside cylinders 17in. by 22in., and two outside cylinders 16¼in. by 24in., giving a total cylinder capacity of 10,125 cubic inches, equal to about 12½ per cent. more than Mersey Tunnel engines referred to by "Nemo." Each pair of cylinders drives its own pair of wheels, 7ft. 6in. in diameter, on the go-as-you-please principle, there being no coupling rods.

(For R. and W. Hawthorn, Leslie, and Co.)
W. Cross, Director.

Forth Banks Works, Newcastle-on-Tyne, December 22nd.

## THE IRON, COAL, AND GENERAL TRADES OF BIRMINGHAM, WOLVERHAMPTON, AND OTHER DISTRICTS.

(*From our own Correspondent.*)

The year which has now closed has been a singularly uneventful one for the iron trade of this part of the kingdom. There have been circumstances which have occurred to break the monotony of the absence of anything like vigorous demand. But these causes of temporary excitement have been quickly exhausted, and, taken generally, the year has been one of the most unsatisfactory that has had to be recorded. The passing of the new and reduced American Tariff Bill, the settlement of colliers' wages in the Federation districts of England upon a basis which is to endure as now up to August, 1896, the circumstances surrounding the history of the Earl of Dudley's Round Oak Iron and Steel Works, Limited, and the final closing and dismantling of the once celebrated and extensive works of the New British Iron Company, are events which loom largest to iron and steel masters hereabouts. As regards iron prices, sheets, both black and galvanised, and gas tube strips are the only departments in the rolled iron branch that have seen much change. Marked iron prices have been unaltered throughout the year, being a repetition in this respect of the experience of 1893; and common and merchant bar prices have fluctuated but slightly. Marked bars opened the year at £7 10s. to £8 2s. 6d., and close the year the same, the best branded hoops being £8, and boiler plates £8 10s. to £9. Common merchant bars opened the year at £6, at which they still stand, and best merchant sorts £6 5s. to £6 10s. A reduction of 2s. 6d. to 5s. per ton appears on common unmarked bars, the £5 12s. 6d. to £5 15s. quoted last January having now become £5 10s. singly. Thin strips and hoops continue at the nominal Association figure which has existed throughout the year of £6 5s. to £6 10s.; but gas-tube strip that was priced at £5 15s. as the Association price a twelvemonth back, may now be freely bought at £5 5s. Sheets of 24 w.g. have lost 5s. to 10s., and 27 w.g. 10s. to £1, while galvanised corrugated sheets have dropped £1 to £1 5s. per ton.

Throughout the first half of the year ironmasters were clamouring for a definite settlement of the coal-trade wages' question by the Federation Conciliation Board. Yet when in July the settlement did come, the improvement in trade which they had been looking for as the result was still absent; or at least was so transitory, that before the end of October it had spent itself. The revival, too, that did occur between July and September was not due to the coal trade settlement, but to the passing of the Wilson Tariff Bill. If anticipations had been realised in the arrival of the marked increase of orders that had been promised—as the context of the United States Customs revision—the "spurt" in trade might have been prolonged. But scarcely any increased demand succeeded.

Pig iron has shown more vitality than manufactured iron throughout 1894. Demand has been better, and prices have been proportionately stronger. Yet even in this department there has been nothing to boast about, and agents of Midland firms especially report the year as one of low prices. Staffordshire pigs opened the year at 95s. to 100s. for cold blast all mine sorts, 57s. 6d. to 60s. for hot blast, 44s. 6d. to 45s. for part mines, and 37s. 6d. to 38s., and occasionally 40s., for cinder sorts. These descriptions of metal now show a reduction of 5s. as regard, all mines, and 4s. 6d. to 6s. on part mines. Northampton, Derbyshire, Lincoln, Nottingham, and similar forge pigs have lost an equal amount. Between July and September, Midland pigs, which had previously been very low, rose 1s. 6d. to 2s. and in some cases 2s. 6d. per ton nominal, but since October the rise has had to be again sacrificed.

A comparison of the bi-monthly returns issued during the year by the accountants to the Midland Iron and Steel Wages Board shows that with the exception of the returns for March and April the selling prices of manufactured iron of all sorts—bars, sheets, plates, hoops, &c., have pursued a uniformly downward course. The return issued in February for the months of November and December, 1893, declared a net average selling price of £6 1s. 3d., and the return which has last been issued—namely, that for September and October—gave the true average at £5 16s. 5d. This last return caused great surprise, showing a drop on the previous two months of 2s. per ton.

Ironworkers' wages, which in February had fallen 2½ per cent., again dropped 2½ per cent., and the men are now being remunerated on this reduced scale, namely, 7s. 3d. per ton for puddling. The total drop in the average selling prices on the year has been 4s. 10d. per ton, following upon a reduction in the average of

4s. 2½d. for 1893, and 1s. 10d. for 1892, and of no less than 10s. 10d. for 1891.

This week the iron trade is quiet, most of the works being closed, and business being generally postponed until the new year. The hope is, however, entertained of considerable orders for iron and steel work in February or soon after, as the result of the decision lately come to by the War-office to construct important additional land fortifications.

The inauguration of active operations by Thomas Parker, Ltd., the new firm of electrical engineers at Wolverhampton, the start of whose extensive works was announced in this report a fortnight ago, seems likely to be rendered memorable by the invention of a new dynamo, for which great things are promised. Only one of the motors has yet been made by the firm, and it is believed that it possesses important electrical developments. It includes the Eickemeyer Patents, the more recent patents in connection with armatures, and new inventions by Thomas Parker, Ltd., which have just been patented. Great attention has been paid to the construction, and a large increase in the power of the electric light is obtained, as well as an advance in the regularity of the service. The dynamo, so far built, will be used to light the whole of the works, both inside and out, but the design, of which it is the earliest outcome, will be regularly employed in the execution of orders.

In a further communication from Mr. T. C. Sharp, of Corporation-street, Birmingham, with reference to the light railways question, this engineer concludes that it is absolutely necessary that the new railways should be owned and controlled by the public. If they are simply commercial undertakings they will, he opines, "soon become absorbed in the great railway monopolies of the kingdom, and thereby not be of the exceptional value to the depressed agriculturist it is intended they should be." Nearly one-third of the English canals are under the control of the railway companies, and therefore cease to be a competitive means of transit. The light railways must, Mr. Sharp thinks, be arranged so that, as well as being feeders to the present railways, they will also be in a position to compete with them. On their own systems they should be able to deliver goods and produce for distances of, say, forty miles around London, twenty miles around other large centres of industry, and about ten miles around the leading market towns. £1500 a mile is, in his opinion, ample for well-constructed tramways beside the highways, where the gradients of the public roads are moderately favourable.

In a report which Mr. E. D. Marten, engineer of the Severn Commissioners, presented to the Committee of Works, on a visit which he has just made to Paris to obtain information regarding the navigating of the Seine by sea-going vessels to that city, he states that no engineering difficulty exists to prevent a line of sea-going steamers being built and worked forthwith to trade between Worcester and Paris and other continental ports. Further, that everything points to such a trade being profitable. The Severn route possesses enormous advantages in the matter of railway competition compared with the Seine route between Rouen and Paris. If the latter can hold its own there is every reason to anticipate that the English scheme could. The distance between Dover and Paris, though only 70 miles as the crow flies, is 150 miles by river, and notwithstanding there is railway competition the whole way, about 4,000,000 tons of traffic were carried on the river in this section last year. This section of the river has been more or less canalised for many years in a similar manner to the Severn between Gloucester and Worcester, by means of nine locks and weirs. In 1878 the State, however, at a cost of £2,500,000, carried out improvement works by which the minimum depth of the channel has been increased from an uncertain 5½ft. to 6ft. to a constant depth of 10ft. 5in. The Severn has been increased by its Commissioners from 6ft. to 10ft. The Seine is now maintained toll free by the State.

I regret to have to record the death of Mr. Moses Bayliss, aged 77, the senior partner in the important firm of Bayliss, Jones, and Bayliss, Victoria Engineering Works, Wolverhampton. For a long time Mr. Bayliss took an active part in the affairs of the firm, but fourteen years ago he retired from active participation, and went to live at Bournemouth. He died a week ago at his residence at Hampstead, London.

## NOTES FROM LANCASHIRE.

(*From our own Correspondents.*)

*Manchester.*—Not more than a very nominal sort of business has been put through during the past week, and with business practically closed for the year, a brief review of the past twelve months' operations will perhaps be interesting. The most remarkable feature of the year has been the almost inappreciable effect, so far as giving any strength to the market, of the prolonged stoppage of production last year, and the three months miners' strike in Scotland this year. In the iron trade business, with the exception of one or two temporary fluctuations, has shown a very steady downward tendency; whilst in the coal trade, notwithstanding a combination of the coalowners to maintain and regulate prices, they have followed a persistent downward course all through the year, and even with pits working short time, stocks have again accumulated in almost as large quantities as ever. Other noticeable incidents have been the important development of the eight hours movement in the engineering trades, and the two years wages settlement in the coal trade, both of which are regarded with but scant favour by employers generally.

In the iron trade there were anticipations—with the commencement of the year—that the stoppage of production during the coal strike would tend to improve the position of makers and manufacturers, and that with the increased cost of fuel lower prices were scarcely possible. During the first two or three months a fairly active business was being put through in all descriptions of raw and manufactured material; but this was mainly due to makers and manufacturers being called upon to complete deliveries of contracts that had been suspended during the miners' strike, and to consumers having so run out their stocks that they were in pressing need of material to cover immediate requirements. For pig iron, makers were able to get advances of 6d. to 1s. per ton, local brands being quoted at 44s. 6d. to 45s. 6d., less 2½; Lincolnshire, 43s. 6d. to 44s. 6d. net cash for forge and foundry, with Middlesbrough about 45s. 4d. net cash delivered Manchester; and Eglinton, 48s. to 48s. 6d. net prompt cash, delivered Lancashire ports. There was, however, an absence of any real improvement in the principal iron-using industries to back up the market, and directly the special conditions which had brought about the increased activity of demand had passed away, there was a gradual relapse into a state of depression, prices steadily receding to an excessively low point. For a time makers, being fairly well sold, endeavoured to hold to their quoted rates, but merchants began to undersell, and makers were compelled to follow to secure what business there was offering, this downward progress going on until well into the second half of this year, when prices had got to so low a pitch that merchants and consumers, in view of the complete stoppage of production in Scotland, owing to the miners' strike, evidently came to the conclusion that any further giving away was practically out of the question. As a result there was a sudden spurt of buying, with an upward move in prices to the extent of about 2s. to 3s. per ton. Lancashire pig iron, which had receded to about 38s. for forge and 42s. for foundry, got up to 42s. and 44s. 6d., less 2½; Lincolnshire, from 37s. 6d. for forge and 39s. 6d. for foundry, to 39s. 6d. and 40s. and 41s. for forge and foundry, and Derbyshire foundry brands to about 45s. and 46s. net cash delivered Manchester, whilst Middlesbrough iron, from 43s. 10d., got up to 45s. 4d., net cash delivered, with Scotch iron prices necessarily very irregular, owing to the stoppage of the blast furnaces and the consequent scarcity of supplies. Although a very considerable weight of buying was put though, the spurt was of but short duration, and at the maximum figures little or no business of any moment was done. Makers, however, being tolerably well sold for two or three months ahead, were for the time being indifferent about further business, but as they had again to come upon the market, prices steadily gave way until the close of the year, when local brands got back to about 41s. for forge, and 44s. for foundry, Lincolnshire to 36s. 6d., and 37s. for forge, and 38s. 6d. to 39s. for foundry, and Derbyshire to about 43s. and 43s. 6d. for foundry, net cash, delivered Manchester. With regard to outside brands, one remarkable feature was the comparatively inappreciable effect which the complete stoppage of the furnaces throughout Scotland during the miners' strike had upon the market here. Eglinton, which had got down to 45s. and 45s. 6d. net cash, delivered Lancashire ports, prior to the strike, scarcely advanced more than 2s. 6d. and 3s. per ton upon this figure, and with the resumption of the output quickly returned to 46s. and 46s. 6d., whilst Middlesbrough, although there was necessarily an increased demand thrown upon this brand when Scotch was withdrawn from the market, did not get up to more than 45s. 4d., and with the close of the year has returned to about 43s. 7d. and 43s. 10d. net cash, delivered Manchester.

Finished iron makers also commenced the year fairly well supplied with orders, and firm for anything like prompt delivery at about £5 15s. for bars, £7 5s. for sheets, and £5 17s. 6d. for random to £6 2s. 6d. for special cut lengths of hoops, delivered Manchester or Liverpool. These prices gradually hardened during the next couple of months, hoop makers advancing their list rates 2s. 6d. per ton. A long spell of extremely quiet trade followed, with an almost complete absence of export, and bars gradually dropped to £5 7s. 6d., sheets to £7, and hoop makers had to take off their advance of 2s. 6d. per ton. Although during August there was some increased business, finished iron only very partially participated in the spurt of buying which came over the pig iron trade, and extreme depression followed throughout the remainder of the year, with forges scarcely working on more than about half their average production, and bars receded to £5 5s., sheets £6 15s., and hoops to £5 15s. for random, and £6 for special cut lengths, delivered Manchester or Liverpool.

Only a very slow sort of business has been reported generally throughout the steel trade during the year. In raw material, hematites, which in January were quoted about 53s. 6d., gradually receded to 51s., less 2½, but with the spurt in pig iron there came also a considerable weight of buying in hematites, some of the better brands getting up to 54s. and 54s. 6d., but they again quickly receded to not more than 52s., less 2½, delivered. Steel billets have also gradually receded from about £4 5s. in January to £3 15s. and £4 net cash for ordinary qualities in December. Manufactured steel has met with a moderate inquiry for general constructive work, but business has only been practicable at low prices, the only appreciable advance which local and district makers were able to secure being during the stoppage of the steel works in Scotland. Steel boiler plates, which in January were being quoted about £6 7s. 6d. to £6 10s., did not get appreciably above this figure, even when Scotch plates were out of the market, and they close this year at £6 2s. 6d. to £6 10s. per ton delivered.

Taking the engineering branches of industry all through, they may be said generally to have been moderately employed during the year, but for the most part establishments have only been kept going from hand to mouth. Some branches have gone through a period of rather severe depression. This has been especially the case in the locomotive building trade, whilst there has been a very serious decline in the shipbuilding industry on the Mersey, several of the yards which have hitherto turned out a large yearly tonnage having practically had no work of any moment whatever, and Messrs. Laird Brothers, of Birkenhead, have been the only shipbuilding firm that has kept up to anything like the average. During the first few months a rather hopeful tone prevailed as to the prospects of reviving activity amongst engineers generally, and most branches were securing a fairly large weight of orders. This, however, soon fell off, and except that establishments here and there have been kept tolerably busy on what may be termed special work, largely for abroad, slackness has more or less prevailed, many establishments having to work largely on stock to keep themselves anything like fully employed. The monthly returns of the engineering trades union societies have also given evidence of the generally unsatisfactory condition of trade, the number of out-of-work members all through the year having been above the average. The Amalgamated Society of Engineers started the year very badly, with 20 per cent. of their membership in this immediate district on the books in receipt of out-of-work support. This, however, was largely due to suspensions for the holidays, and at the close of the month the number had got down to about 10 per cent., the Steam Engine Makers' Society having about 6½ per cent. on donation benefit. During the next few months the number of unemployed members slightly decreased, the Amalgamated Society of Engineers getting down to about 9 per cent. and the Steam Engine Makers' to about 5 per cent. of the local membership in receipt of out-of-work support. There was, however, again an increase, the Amalgamated Society of Engineers getting back to about 10 per cent. of the membership in receipt of donation benefit, but with the close of the year there has been a slight but steady decrease, which is regarded by the trades' union societies as a satisfactory indication that with the ensuing spring there may be some revival of activity.

In the coal trade the year commenced with collieries generally altogether without stock, as the result of the previous four months' stoppage of the pits. The exceptional mildness of the weather and the depressed condition of the principal coal-using industries both, however, operated to prevent any real strain upon the market as regards supplies, which very quickly became plentiful, and prices, which it was hoped there would be no difficulty in maintaining at some substantial advance upon the low rates ruling prior to the strike, commenced a steady downward course until they touched as low if not a still lower point than those ruling when the coalowners felt themselves under the necessity of giving notices for a 40 per cent. reduction in wages. Housefire qualities have been in exceptionally poor demand all through the year, and before last winter had closed heavy stocks had accumulated. Prices, which in January had been fixed at something like 15s. for best Wigan Arley, 13s. for seconds Arley and Pemberton four feet, and 12s. for the commoner qualities of round coal, have steadily receded right on to the close of the year, when best Wigan Arley is scarcely fetching more than 10s. 6d., seconds Arley and Pemberton four-feet 9s. to 9s. 6d., and common house coals 7s. to 7s. 6d. per ton at the pit, these prices being quite 1s. under even those which were being quoted in July, and the leading Manchester firms have been under the necessity of reducing in December the "lowest summer rates" which they were quoting in October and November. The commoner qualities of round coal have also been in but very indifferent demand for iron making, steam, and general manufacturing purposes, and although during the Scotch strike large quantities were sent away into Scotland, for the time being clearing away a good deal of the surplus supplies, and enabling some of the collieries to work full time, no very appreciable advance in prices was, even during this period, obtainable, the effect being little more than to check the downward tendency of the market. Steam and forge coals, which in January were being quoted about 10s. to 10s. 6d., have gradually receded, until with the close of the year they do not average more than 6s. 6d. per ton at the pit mouth, and for shipment even as low as 5s. 6d. to 6s. is being taken. Engine classes of fuel have fluctuated somewhat, as supplies have been regulated by the demand for round coals, and during the earlier part of the year began to tend upwards, owing to the restricted production of slack, the better qualities getting up to 6s. 6d. and 7s. and common qualities to 5s. and 5s. 6d. at the pit-mouth; with however, the increased demand for round coal for shipment to Scotland during the miners' strike, supplies of engine fuel became plentiful, and soon a complete drug owing to the general restriction of requirements for manufacturing purposes, with the result that prices have steadily receded until common qualities of slack have got down to about 3s. and 3s. 6d. and the better qualities about 4s. 6d. and 5s. at the pit mouth. More than ordinary importance has been attached to the usual gas coal and locomotive fuel contracts during the year, as it was alleged by the officials of the Miners' Federation that the needlessly low prices taken for these in previous years had been the main cause of the demand for a reduction in wages. With a view of regulating prices generally, but chiefly with the object of preventing, if possible, needlessly keen competition for these contracts during the ensuing season, a combination of Lancashire coalowners was formed soon after the resumption of work at the collieries, and a sort of agreement was come to with the Yorkshire coalowners not to tender under the 1892 prices, which would have represented an advance of about 1s. per ton on the basis of the 1893 contracts. Early in the season one or two contracts were placed at advances of 6d. to 1s. per ton on 1893 prices, and a strong feeling was expressed that the gas coal collieries should hold out for a substantial advance over last year's basis, but this was soon found to be impracticable. With regard to the important Manchester gas coal contracts, an arrangement was come to that tenders should not be sent in except at prices 6d. above those of the previous year, but these contracts were ultimately settled on practically the basis of the 1893 rates. As the season advanced other large contracts had to be taken at very much the same prices as in 1893, and except upon a few of the smaller contracts, the maximum general advance maintained did not exceed 3d. per ton over the low prices of 1893. For the locomotive fuel contracts coalowners did rather better, and in some cases advances of 6d. to 9d. per ton on the previous year's rates were obtained.

*Barrow.*—There is still a very quiet tone in the hematite market, and orders are not offering to any marked extent. There has practically been no business done this week, as the holidays are being observed generally, a remark which applies as much to industrial as to commercial matters. Makers have fewer orders in hand than even at this time last year, when trade was admittedly dull; and although only 31 furnaces are in blast out of 75, and compared with 33 in the corresponding period of last year, stocks are gradually increasing, and now stand at about 175,000 tons, compared with 94,000 tons this time last year. Prices are easier at 42s. per ton net sellers, and 42s. 9d. buyers. Makers are quoting 43s. 6d. to 44s. for mixed Bessemer numbers, net f.o.b.

Iron ore is in quiet demand. Indeed the local consumption, which is the mainstay of the trade, has fallen off lately. Prices are easy at 8s. 6d. for ordinary and 13s. 6d. for best sorts net at mines.

The steel trade is practically at a standstill. Makers are fairly sold forward in plates, but in rails and tin bars very little is doing, and in other branches of the trade orders are, generally speaking, either very scarce or absolutely nil.

Shipbuilders and marine engineers remain very busy. A rather long holiday is being observed at local yards, but there is any amount in hand for the New Year, and it is confidently expected there will be a renewal of orders next year as the work in hand gets finished.

Coal and coke are a very poor and quiet market, and the consumption lately has been much below the average of previous years. Prices are steadily maintained.

Shipping is very quiet, and the recent storm has accentuated the depression. Cargoes are few, and freights are at low and unprofitable rate.

## THE SHEFFIELD DISTRICT.

(*From our own Correspondent.*)

During the last few days business in the South Yorkshire coalfield has been somewhat better, owing to the orders for prompt delivery having been more numerous. Prices are firmer, although there is no possibility of making more money. The Christmas season requirements, which have now passed, have had a good deal to do with the improved trade, which will only be of short duration unless the weather changes. The metropolis has been taking a fair average tonnage of Silkstones and thick seam coal. The demand, however, still continues dull, sales being slow, and the competition of seaborne coal causing prices to remain very weak. The improved business with London was no doubt owing to the anticipated stoppage during the holidays, rather than to any real advance in trade. Eastern counties are taking but a poor tonnage. Quotations are as follows:—Silkstones, 9s. 6d. to 11s. per ton; Barnsley House, 8s. 3d. to 9s.; Flockton, 8s. to 8s. 3d.; and thin seam coal, 7s. to 7s. 6d.

The steam coal trade continues in a fair state. Considering that this is the last month of the year, the tonnage sent to Hull and the other Humber ports is good, the open weather favouring the sale of bunker coal. The Hull and Barnsley Railway is taking more than the average at this period of the year. Grimsby is also taking a fair amount, but considerably less is being sent to Goole.

Quotations range from 7s. 6d. to 8s. for best qualities of steam coal, and 7s. to 7s. 3d. per ton for secondary sorts. Railway companies in this locality are generally receiving heavy supplies of coal, under contract arrangements. The North-Eastern Company have placed a considerable portion of their contracts for locomotive coal. Part of the business has come into South Yorkshire, the prices obtained ranging from 7s. 6d. to 7s. 9d. per ton, free on rails at the pits. It is understood that the Durham coalowners, in making their arrangements to supply the same company, have fared rather better, the prices they have secured varying from 7s. 9d. to 8s. per ton. These rates exhibit a decline of about 1s. a ton as compared with last year. Gas coal is in large demand at from 7s. to 8s. per ton. Manufacturing fuel is in a better request, supplies being less abundant owing to the shorter time worked at the collieries. Riddled slack makes from 5s. to 6s. per ton, and unriddled or ordinary pit slack fetches about 3s. per ton at the pits. The coke trade is in a fairly good condition and prices range from 9s. to 11s. per ton, a large quantity being forwarded to Derbyshire, North Lincolnshire, and adjoining districts.

The decline in the value of steam coal is rather a serious factor in the South Yorkshire coalfield, of which it constitutes so large a part. The rates now ruling are lower than that which prevailed when the miners received their second 10 per cent. advances in 1889. The price was then 8s. 6d. per ton. In 1890-91 the North-Eastern Railway Company paid 11s. per ton of 21 cwt.; then values fell by about 1s. per ton per year until the stoppage of last season altered everything. Again, coal is falling through the all-powerful reason of supply exceeding demand.

Business for the year is now practically at an end. Some of the works were opened on Monday, but generally the trading operations of 1894 terminated last Saturday. With the single exception of armour-plates, it has been a decided disappointment in all the heavy industries. In regard to iron, West Coast hematite pig was at 53s. 6d. in January of 1894, as compared with 55s. in the corresponding month of 1893. On April 1st the value remained at 53s. 6d., against 52s. 6d. in April of the previous year. On July 1st the price dropped to 52s. 6d., which was the same rate as was quoted in July of 1893. This rate was continued during October, but dropped to 52s. on December 18th, at which figure it still stands. In October and December of 1893 the prices were 52s. 6d. and 53s. These quotations refer in every instance to West Coast brands. East Coast iron can be bought at about 2s. per ton less. Common forge iron on January 1st was 40s. 6d.; on April 1st, 40s.; July 1st, 39s.; October 1st, 38s.; December 21st, 38s. At the corresponding periods of 1893 the prices were 39s. 6d., 38s., 38s., 40s.—during coal strike—and 41s. Prices are very weak at the present time. Stocks have been increasing for the past two months.

In armour during 1894 orders have been placed by the English Admiralty with the three Sheffield firms for about 18,000 tons of Harveyed steel plates, the armour being required for the battleships Magnificent, Majestic, Victorious, Prince George, Hannibal, Jupiter, and Mars, and the cruisers Powerful, Terrible, Dido, and Isis. The armour for two Japanese battleships, altogether about 4600 tons, has also been ordered from Sheffield during the past year. Railway and marine material has been in very light request. Not one-third of the productive plant has been employed during the year. Altogether there is very great depression in the general trade, but for some weeks past commercial men have been encouraged by the prospect of inquiries coming forward at the commencement of the New Year from our Colonies—India, South Africa, Australia, &c., and hopes are entertained that the Sheffield houses will be doing at least a greater volume of work during the year 1895 than in that now drawing to a close.

Only two features of the lighter staple trades call for special mention. The settlement of the American tariff has doubled the business done in cutlery with the States during the last three months. In the quarter ending June the total value of cutlery exports to the States was only £6518. In July, the last month under the McKinley tariff, the value was £4822. The new duties came into force in August, and cutlery at once rose to £21,892, and in September to £15,962—a total of £42,677 for the third quarter of the year, against £25,146 for the similar period of 1893. Steel also rose to £52,089, against £40,613 for the corresponding quarter of 1893. The figures for the last quarter of the year will not be obtainable until the beginning of January; but the United States Consul here has been good enough to get them out for me as far as they have gone. The exports for October last are as follows:—Cutlery, £15.928; steel, £22,553; for November, cutlery, £18,691; steel, £29,499. The trading for December shows that the results will compare favourably with that for October and November.

The other point is the preference given to silver goods, owing to the low value of the sterling metal during 1894. Silver has never been so cheap, and this has encouraged householders to pay the little extra sum for the luxury of real silver appointments.

## THE NORTH OF ENGLAND.

(*From our own Correspondent.*)

THE year is closing with business very quiet; but, on the whole, traders are more sanguine about an improvement next year than they were a month ago—though it must be acknowledged that they do not take as rosy a view of the situation as they did at this time last year. The better tone is brought about by the greater activity in shipbuilding, owners this month having given out orders more freely for new vessels, and it is expected that 1895 will be a brisker year at the shipyards than the closing year has been. Last week Messrs. Blumer and Co., Sunderland, obtained an order for a 3000-ton cargo steamer; and Messrs. William Gray and Co., West Hartlepool, have contracted to build two large steamers, for the carriage of oil and general cargo. Messrs. Doxford, Sunderland, have been commissioned to construct two more steamers of the turret type—of which they were the originators—and on which principle they have built eleven steamers. Most firms will begin the new year with a larger number of orders than last month they had reason to look for, and this is very favourably influencing various departments of the iron and steel industries, inducing traders to believe that we have seen the worst of the depression. The year just ending has been a moderately satisfactory one for shipbuilders in respect to the amount of work they have executed, but as prices have been very low, profits will have been extremely small; indeed, by reason of strikes, many vessels will not have been built for the money the shipbuilder received for them. The output at the shipyards this year has exceeded that of last year, but it falls a good deal short of what could have been executed if trade had called for it. When, however, we consider how seriously operations were hampered at the shipyards during the spring and summer because of the prolonged strikes of moulders, engineers, and patternmakers, it is surprising to see the production as large as it is in this district. There have been no strikes of any moment in the shipbuilding trade proper, all disputes being settled amicably, but the strikes of men outside this particular trade have sadly affected it, for the supplies of castings giving out through the strike of moulders, operations at the yards had in many cases to be suspended for a time. We must characterise these strikes of moulders and patternmakers as disastrous failures—the men after remaining out for nearly half a year for heavy advances of wages, having to resume at the old rates of wages. There was never from the very first any likelihood of the strikes being successful, for the trade was going back instead of improving, and the engineers who also came out quickly recognised the hopelessness of the fight and went back to work where they could get it. The men will have learnt at great cost the lesson that they cannot coerce the market—they cannot force advances of wages if selling prices are declining and work is scarce.

Yet, in spite of these strikes, the output of tonnage at the shipyards on the North-East Coast this year in each district shows a considerable advance, that on the Tyne being 43,415 tons; on the Wear, 44,713 tons; on the Tees, 6718 tons; at the Hartlepools, 12,552 tons; at Whitby, 31 tons; and at Blyth, 2034 tons, a total increase of 109,463 tons as compared with last year. The following table shows the total tonnage of vessels launched on the North-East Coast during each of the last five years:—

| | 1890. Tons. | 1891. Tons. | 1892. Tons. | 1893. Tons. | 1894. Tons. |
|---|---|---|---|---|---|
| Tyne .. .. .. | 234,866 .. | 185,257 .. | 207,211 .. | 147,249 .. | 190,664 |
| Wear .. .. .. | 193,893 .. | 192,150 .. | 190,775 .. | 121,790 .. | 166,503 |
| Tees .. .. .. | 127,740 .. | 121,032 .. | 99,279 .. | 95,115 .. | 101,833 |
| Hartlepools .. | 99,847 .. | 96,983 .. | 90,924 .. | 76,641 .. | 79,183 |
| Blyth .. .. .. | 7,377 .. | 7,005 .. | 8,071 .. | 2,225 .. | 4,260 |
| Whitby .. .. | 8,682 .. | 4,781 .. | 13,267 .. | 2,784 .. | 2,753 |
| | 672,405 .. | 606,392 .. | 609,477 .. | 445,805 .. | 545,206 |

The improvement reported in shipbuilding this month is leading to a better demand for plates and angles, and this is extending to the hematite pig iron trade, but this week, owing to the holidays, there is very little buying. Prices certainly are firmer. Last week some No. 3 Cleveland g.m.b. pig iron was sold by merchants at 35s. per ton—the lowest price of the year, but this brought in a lot of people anxious to purchase, and the price was advanced again until now not less than 35s. 3d. per ton will be taken. There are plenty of consumers ready to buy for delivery over the first three months of next year at 35s., but sellers will not accept that, and it seems to be thought that prices are now as low as we are likely to see them. The warrant market has been closed for two days this week, but prices have been stronger than last week, Cleveland warrants having advanced to 35s. 2½d. No. 4 Cleveland foundry pigs are stiff at 34s. 6d. and grey forge at 33s. 6d. Makers of hematite pig iron in this district expect to find business more tolerable next year, because a heavier demand will follow the improvement in the plate and angle trades, and besides this the price of foreign ore is easing owing to the decline in the rates of freight. Owners of steamers have taken as low as 4s. 7½d. Bilbao-Middlesbrough, where during the summer they got 5s. 6d., and only last month 5s. 1½d. Good Rubio ore can now be bought at 11s. 10½d. delivered on Tees, a price which can leave little to the merchant who has to pay 7s. for the ore f.o.b. at Bilbao. Over half a million tons have just been sold at that figure for delivery over the next quarter.

Most of the finished iron and steel works are closed this week for the holidays, but manufacturers expect when they resume operations to be more regularly employed than they have been in the current quarter. Iron and steel ship-plates are quoted at £4 15s., and iron and steel angles at £4 10s., both less 2½ per cent. and f.o.t. The improvement is not likely to be so much felt in the iron as in the steel-plate trade, because so few of the vessels are built of iron now. Manufacturers would much rather have orders for steel than iron-plates at the above-named price, for the latter cost more. Common iron bars are steady at £4 17s. 6d., less 2½ per cent. f.o.t., and producers are fairly supplied with work for next month. The Tees-side Iron and Engine Works Company, Middlesbrough, have secured an order for about 1000 tons of bridge work, &c., for India. Bridge builders generally are fairly well occupied, as are also the wagon builders. Marine engineers are not doing well, but expect to share in the improvement in the shipbuilding industry. Meantime they are turning their attention more to the production of engines for other work, such as for driving dynamos, rolling mill machinery, &c.

On Wednesday the death took place of Mr. William Middlemass, of Middlesbrough, one of the most extensive of ore importers in the North of England. He was a native of Alnwick.

The coal trade is quiet on the whole, but the output is larger this week than is usual in Christmas week, for a large number of miners are not taking their usual week's holiday. The deliveries on the whole are restricted, as less manufacturing and house coal is required. The consumption of manufacturing fuel has been lessened by the stoppage of so many works, and the extraordinarily mild weather accounts for the poor sale of house coal. Best steam coal is about 9s. per ton f.o.b., and small 3s. 6d. to 4s. The Durham Coal Sales Association keep up the price of gas coals to 7s. 3d. f.o.b. There are now thirty-four of the leading firms connected with this association, and outsiders practically adopt the syndicates' prices. The price of coke is also ruled by a sellers' combination, which maintains it at about 12s. 3d. per ton, delivered to the furnaces on Teesside, a figure considerably above what has formerly been paid when pig iron prices were about the present rates. But as long as the present number of furnaces is kept in operation, and there is no decrease in the consumption, coke is not likely to be reduced in value.

## NOTES FROM SCOTLAND.

(*From our own Correspondent.*)

THERE has been comparatively little doing in the iron market this week. Business was completely suspended on Christmas Day and the day following, and on the other days of the week the meetings on 'Change in Glasgow were largely formal, with little disposition to buy or sell. The transactions in Scotch warrants were at 41s. 11d. to 42s. cash, and in Cleveland 35s. 1d. to 35s. 1½d. No speculative business is recorded in hematite, and the nominal quotations are for Cumberland warrants 43s., and Middlesbrough 42s. cash.

The furnaces in blast number 71, the same as last week, compared with 28 at this time last year, and there are 25 making hematite and 46 ordinary pig iron.

The week's pig iron shipments were 4310 tons, against 2944 in the same week of 1893.

For makers' special brands the demand is quiet, and the prices in several instances are about 6d. lower. G.M.B., f.o.b. at Glasgow, No. 1, is quoted 43s. per ton; No. 3, 41s. 6d.; Monkland, No. 1, 44s. 6d.; No. 3, 41s. 6d.; Carnbroe, No. 1, 45s. 6d.; No. 3, 43s. 6d.; Clyde, No. 1, 49s. 6d.; No. 3, 46s. 6d.; Gartsherrie, No. 1, 51s. 6d.; No. 3, 47s.; Calder, No. 1, 51s. 6d.; No. 3, 47s. 6d.; Summerlee, No. 1, 53s. 6d.; No. 3, 47s. 6d.; Coltness, No. 1, 54s. 6d.; No. 3, 50s. 6d.; Glengarnock at Ardrossan, No. 1, 50s.; No. 3, 47s.; Eglinton, No. 1, 47s.; No. 3, 45s.; Dalmellington at Ayr, No. 1, 47s.; No. 3, 45s.

The shipments of pig iron from Scottish ports in the past week amounted to 4310 tons, against 2944 tons in the same week of 1893.

In the manufactured iron and steel branches few transactions have been taking place this week. The demand is quiet, and values unaltered. The shipments of iron and steel manufactures from Glasgow embraced sewing machines to the value of £9271; other machinery, £12,814; steel goods, £12,483; and general iron goods, £30,540.

There is a quiet business in coals; about former prices. The home demand is practically met until after the New Year holidays, and the export business is inactive. The past week's coal shipments from the whole of the Scottish ports reached 136,037 tons, which shows an increase of 5201 tons compared with those of the preceding week, but is 38,328 tons less than in the corresponding week.

## WALES AND ADJOINING COUNTIES.

(*From our own Correspondent.*)

THE tradition of the coal trade, of a spurt before Christmas, and increased activity at all the collieries, steam and house, have been well maintained. Coalowners and shippers are well aware that, when the collier begins his national holiday, there is no dependence upon a speedy resumption of work, and so a pressure is put on to get as much coal out and shipped as possible, and the last week's arrivals show this in a marked degree. At the collieries, on the various lines, and at the ports, good energetic work has been the leading and predominant feature.

Newport showed a good deal of vigorous work. Swansea totalled 50,000 tons instead of its usual averages, which rarely touch 40,000 tons; and the ports of Cardiff, in which I include Barry, sent away the enormous quantity of 325,000 tons. In stating this, it will be seen that at the collieries, and at ports, there was a great degree of activity shown, and it is as certain that this week will afford a very considerable contrast.

The opinion on 'Change, Cardiff, on Monday, was that the great spurt of last week must not be taken as showing improved prospects, good authorities, commenting upon the condition of things, and regarding especially the unsettled views of the colliers respecting the sliding scale, considered the outlook as rather a gloomy one. The business now in hand for January is meagre, unless a speedy alteration takes place, and prices are weaker. Best steam this week is quoted in Cardiff at 11s., good seconds 10s. 3d. to 10s. 6d., and good dry coal 9s. 9d. to 10s., small 4s. 6d. to 5s.

In the matter of house coal it is still not up to the expectations of the principal men in the trade, and the shortest day has been passed without the usual improvement in price. One cause of this is the mildness of the season, and hopes are held out that if this be the only cause, the next three months may bring about a change and improve matters. The best house coal is now only realising from 10s. 9d. to 11s. Cardiff. No. 3 Rhondda sells at 10s. 3d., brush 8s. 6d., small 6s. 6d., No. 2 Rhondda 8s. 9d., thorough 6s. 6d., small 4s. 6d.

In patent fuel there has been increased activity at all ports, especially Swansea, and I am pleased to note that makers are well booked ahead, and prices firm at 10s. 9d. to 11s. Cardiff. So, too, in coke, but while there is more briskness in this trade prices remain, the latest Cardiff being 14s. to 15s.; furnace, foundry, ordinary 15s. to 16s., and special 21s. to 21s. 6d. Swansea anthracite quotations remain at 12s. 3d. to 12s. 6d. for best malting samples.

The best feature of last week in the tin-plate district of Swansea was the great shipment that took place, amounting to 138,865 boxes, or 8000 tons. This made a serious inroad upon stocks, which are now down to 226,000 boxes. There was a large quantity brought from works, 83,325 boxes, and yet I am unable to chronicle any improved signs. Wage questions are still in abeyance in many places, and prices are in the old rut. It will be well, however, to suspend opinion for another week or two, and to note especially if shipments show a steady, not a spasmodic character.

The large consignments of tin-plates from Swansea last week indicated a greater degree of briskness at the steel works, the Cyfarthfa Works in particular exceeding last week their ordinary average make of steel bar. In other branches little has been doing worth noting, the only rails despatched of late have been under 200 tons, principally to Highbridge, on Great Western account.

Iron and steel quotations remain with scarcely the slightest change. In rails a small reduction is perceptible, and instead of £3 12s. 6d. being quoted as the lowest, £3 11s. 6d. is named for heavy rails. This shows how closely makers are "cutting." In Bessemer bars also there is a little difference, and instead of £4 being the minimum, makers quote £3 18s. 6d. to £4, and Siemens best bars at £4 2s. 6d.

I shall not be surprised, as the tin-plate outlook improves after a time—and at the time of my dispatch I hear of important works having come to terms at Llanelly with their men—that an endeavour will be made to get important forward booking at these prices; which certainly are as low as it is possible to get, and could only be managed by a low-wage market.

The wages settlement in the tin-plate trade, to which I have referred, will, I hope, be a precedent for all other works, so that uniformity of price and wage can be maintained. It was brought about at a meeting held in the Athenæum, Llanelly, on Sunday evening. The masters' offer of a 10 per cent. reduction was, after a discussion, agreed to, and now only one trifling matter remains, which is not expected to upset the arrangement; this is that the masters want the men to work forty boxes per shift, and the men only wish to do thirty-five.

The iron ore trade continues very quiet. Best Rubio is now obtainable at 11s., and Tafna and Garucha are quoted at 10s. 6d. to 10s. 9d. The principal ore imports of the week have been, one cargo to Blaenavon, and two to Dowlais.

There was a general meeting of colliers' representatives on Monday at Cardiff, under the presidency of Mr. D. Morgan. With reference to the new society or Union, which is being worked up, the chairman observed that in six months' time it would be composed of between 40,000 and 50,000 members. The society is to be called "The Amalgamated Society of the Colliery Workmen of the South Wales Coalfield," which is about as blundering a title as could be given. A simpler one could easily be named. During the meeting the rules were all reported as passed, and the officers elected. Mr. D. Morgan becomes president, Mr. Grace vice-president; Mr. J. Williams, Ynysybwl, secretary; and Mr. Onions treasurer.

With reference to the contention about the Albion funds, a committee has been formed to endeavour to get concessions from the Provident Fund, but so far no arrangement has been brought about. The committee of the Provident are willing to give an additional 50 per cent. to the Albion widows and orphans if the outstanding monies are paid into their hands, and this is how the question is left at present.

I hear that a meeting will take place in the course of a few days between the selected members of the colliers' representatives on the sliding scale and Mr. Dalziel, secretary of the Coalowners' Association, in order to discuss the revision of the agreement, and all must cordially hope that a peaceable arrangement will be brought about.

## NOTES FROM GERMANY.

(*From our own Correspondent.*)

THE best that can be said of the iron trade in general is that during the week now past no further reductions in price have taken place, and that taking it all through a moderate but rather regular employment has been maintained at the works.

The news received from the Silesian iron market is still anything but good, although a slightly better feeling has been perceptible in some instances, which may be accounted for by a temporary improvement in the demand for some special articles of manufactured iron.

There is little of interest to note in connection with the Austro-Hungarian iron and steel trades. Consumers have been very slow in placing orders, and there is consequently an exceedingly weak tone in the quotations for most articles. The only branch with a little more life in it is the hardware business, demand in Austria and Bohemia and also in the Vienna market having slightly improved upon the week.

In France demand and sale have partially improved; on the whole, however, business on the iron market is dull, and only a very small number of substantial orders have been received at the works. Concerning the condition of prices in the different departments, the general tone is, if anything, rather more weak than formerly.

There is scarcely any change noticeable in the situation of the Belgian iron industry, a quiet tone prevailing in all branches. Official quotations have not altered since former letters. Import in pig iron amounted to 4463 t. in October of present year, against 7237 t. in the year before, and against 4769 t. in 1892. During the first ten months of present year 174,945 t. were imported, against 106,661 t. for the same period the previous year, and against 113,584 t. in 1892. The figures of import in pig iron from Germany are 32,836 t., 27,274 t. and 28,991 t. for the present year and the two preceding years.

The Belgian coal trade shows decidedly more firmness, owing to the cold weather which set in last week. Stocks have been almost cleared in some instances, especially those of medium sorts. Prices for all classes of fuel are maintained with much firmness, and concessions are but rarely agreed to now. In the Moirs district small coal fetches 7·50f. p.t.; house coal, 9f. p.t.; best steam, 11·50f. p.t. In the Liège district higher prices are obtained, best house coal being paid with 13f. to 14f. p.t. Engine classes of fuel are somewhat neglected of late. Export in artificial coal has again considerably increased; in October 46,511 t. were exported, against 26,757 t. in previous year, and against 31,080 t. in October, 1892. Export in artificial coal during the first ten months of present year was 488,392 t., against 397,663 t. for the corresponding period last year, and against 248,121 t. in 1892.

The blast furnace works in the Siegerland report a good amount of fresh orders coming in, some of the larger rolling mills having already covered their demand for the first two quarters of 1895. Prices noted upon the week are: for spiegeleisen, 10 to 12 p.c. grade, M. 51 p.t.; Rhenish-Westphalian forge pig, No. 1, M. 46 p.t.; No. 3, M. 42 p.t.; Siegerland good forge quality, M. 44 p.t.; hematite, M. 63 p.t.; foundry, No. 1, M. 63 p.t.; No. 3, M. 54 p.t.; basic, M. 45 p.t.; German Bessemer, M. 50 to 51 p.t.; iron, for making steel, M. 45 to 46 p.t.; Luxemburg forge pig, 48f. p.t., free Luxemburg. Considerable depression still exists in the malleable iron department, the demand for bars and girders becoming more flat from week to week. Hoops are in pretty fair request, both dealers and consumers buying rather largely at the present reduced quotations. The plate and sheet mills are only partially well occupied; sheets especially meet with an extremely poor request. Wire and wire nails, as well as rivets, continue very dull; even the lowest offers fail to attract the buyers.

Construction shops as well as iron foundries continue, on the whole, but insufficiently employed. Latest list quotations, per ton at works, are as follows:—Good merchant bars, M. 100 to 105; angles, M. 110 to 115; girders, M. 85 to 90; hoops, M. 105 to 108; billets in basic and Bessemer, M. 73 to 77; heavy plates for boiler-making purposes, M. 140 to 145; tank ditto, M. 130 to 135; steel plates, M. 120 to 125; tank ditto, M. 110 to 115; sheets, M. 115 to 130; Sieger thin sheets, M. 120 to 125. Iron wire rods, common quality, M. 92 to 107; wire nails, M. 113 to 115; rivets, M. 145 to 150; complete sets of wheels and axles, M. 270 to 280; axles, M. 220; steel tires, M. 215 to 230; steel rails, M. 108 to 110; steel sleepers, M. 106; fish-plates, M. 112 to 120.

The works of the Saar and Mosel district produced in November, 1894, 28,333 t. forge pig; 58,128 t. basic; and 7022 t. foundry, together 93,483 t. Output is higher by 0·5 p.c. than that of the preceding month of October, when it was 92,999 t. only. In November, 1893, total production was 85,156 t., showing an increase of 9·8 p.c. for same month this year.

## AMERICAN NOTES.

*(From our own Correspondent.)*

NEW YORK, December 18th.

A FATALLY defective currency scheme is to be carried through Congress, which will actually destroy the present national banking system. The Government have lost fourteen million dollars in gold since the bond sales, and another sale is contemplated. General business is now 7 per cent. better than a year ago, but 14 per cent. less than two years ago. An improvement in the iron trade is probable next month. Pig iron production is increasing, and is now 170,000 tons per week against 195,000 tons—the maximum production in good times. The turning point in the manufacturing situation will be reached when the railroads begin to buy and build. There are 175,000 miles of road in need of equipments, and not less than 25,000 miles of projected road to be built. If enterprise dare manifest itself without fear, a pig iron production of eleven million tons will barely meet the requirements. Forge iron is quiet. Inquiries are numerous for billets. Considerable structural material is in demand for delivery during the first quarter of the year.

## IRRIGATION SETTLEMENTS IN AUSTRALIA.

AT the monthly meeting of the Leeds Association of Engineers, the president—Mr. S. Thornton—in the chair, Mr. Henry McLaren, M.I.M.E., read a paper on "The Chaffey Bros.' Irrigation Settlements in Australia." He said that in 1885, Messrs. Chaffey, the leading exponents of irrigation in South California, were invited to visit Victoria with the object of founding a settlement there similar to those in America. Active operations were commenced in October, 1887. With the aid of maps Mr. McLaren explained the scheme of irrigation at Mildura, which, like the sister colony — Renmark — is advantageously situated on the Murray River. No fewer than 25,000 acres are at present laid out; about 15,000 acres have been sold, and 10,000 are under cultivation.

The needs of the irrigators are met by a system of open earthwork channels, conveying the river water to their various allotments, where it is sluiced into ploughed furrows and allowed to permeate the soil. The pumping engines represent 2450 horse-power, the pumps having a capacity of 50,000 gallons a minute. The methods employed in clearing the virgin soil of the eucalypti and other native trees, the processes of scarifying and planting, and the cultivation and treatment of citrous fruit up to stoning, drying, and packing, were severally explained, numerous photographic enlargements serving the purpose of illustration. Fruits such as grapes, figs, oranges, lemons, plums, almonds, apricots, apples, peaches, pomegranates, quinces, passion fruit, &c., are grown in separate orchards, which being laid out geometrically and under constant cultivation, present a strangely beautiful appearance, whilst the homesteads of the English settlers are surrounded by a paradise of fruit and flowers.

Nothing could be more remarkable than the rapid growth of vegetation and the prolific yield of fruit. In six years the land has not only been cleared and planted, but the trees have reached mature size, producing several crops a year, their number being regulated by the frequency of periodic irrigation. During the last season the output from Mildura alone represented a value of £50,000. A population of 3500 is now settled in the colony, including about 500 school children. Mr. McLaren said that there was money in the undertaking so far as the fruit growers themselves were concerned. A discussion followed, in which Messrs. Thornton, Towler, Bowers, Lupton, and Atkinson took part.

NAVAL ENGINEERING APPOINTMENTS. — The following appointments have been made at the Admiralty:—Staff engineer: James J. Frost, to the Sybille. Chief Engineer: W. Pleming, to the Dryad. Engineers: R. St. J. Raper, to the Skate; Charles E. Shorey, to the Contest. Assistant engineers: Edward E. Lewis, to the Hood; Frank S. Moss, to the Dryad; J. B. Huddy and F. A. Gordon (Proby.), to the Sybille.

HULL AND DISTRICT INSTITUTION OF ENGINEERS AND NAVAL ARCHITECTS.—On Monday evening, the 17th inst, Mr. R. B. Kennedy, of Grimsby, read a paper on "Mechanical Refrigeration, with an Outline of its Application," before the members of the above Institution; the President, Mr. F. H. Pearson, being in the chair. Refrigeration dates as far back as 1550, in which year a Roman physician produced an artificial reduction of temperature by dissolving saltpetre in water. In 1607 a combination of snow and saltpetre was used for maintaining low temperatures, and to-day a similar mixture, *i.e.*, pounded ice and common salt, is used for the same purpose in most towns by the ice cream vendors, &c. In the course of the paper Mr. Kennedy explained the various mechanical processes of refrigeration, including the dry rarefied air machine, cold air compression machine, and the gaseous, or liquid, compression and absorption processes, in which anhydrous ammonia, sulphurous oxide, carbonic acid, or ether are largely used by the various manufacturers. The vacuum system, and the two methods of utilising cold, viz, the brine and direct expansion systems, had to be omitted through want of time. The application of refrigerating machinery for cold storage, meat freezing, ice making, extraction of paraffin, brewing, distilling, chocolate making, cooling rooms, hospitals, &c., were then gone into, and many interesting details given as to imports which refrigeration has made possible, such as meat, fruit, butter, eggs, &c. The Australians appear at last to have discovered a method of utilising the rabbit pest, for now large quantities are being killed and forwarded to this country in cold storage vessels, and have so far realised a handsome profit. In the discussion that followed the following gentlemen took part:—Messrs. F. H. Pearson, S. Simpson, W. B. Dixon, and A. N. Somerscales, the lecturer replying to the points raised. At the close a hearty vote of thanks was accorded Mr. Kennedy for his able and most interesting paper.

## THE PATENT JOURNAL.

*Condensed from "The Illustrated Official Journal of Patents."*

### Application for Letters Patent.

*** When patents have been "communicated" the name and address of the communicating party are printed in italics.

*11th December*, 1894.

24,064. SPINNING FLAX, R. H. S. Beade and H. McKibbin, Manchester.
24,065. MACHINERY for DRYING GRAIN, C. Mallinson, Liverpool.
24,066. UMBRELLAS, S. G. Rawson, Liverpool.
24,067. ORGANS, &c., R. Hope-Jones, Liverpool.
24,068. AUTOMATICALLY LOCKING CARRIAGE DOORS, J. Trantom, Liverpool.
24,069. CLOSING DEVICE for WATER PASSAGES, H. Kägi, Liverpool.
24,070. SUPPLYING AIR in DRYING MACHINES, J. Higginbottom, Liverpool.
24.071. MANUFACTURE of BARRELS, &c., J. Polke, London.
24,072 WIRE MATTRESSES, H. Reinhold, London.
24 073. WRAPPING MACHINES, I. R. Hutchinson, London.
24,074. FLUID METERS, A. J. Boult.—(*Hegenscheidt Bros. and T. Derichs, Belgium*.)
24 075. REGULATING ELECTRIC DYNAMOS, T. D. and F. W. Hollick, London.
24 076 TELEGRAPHIC TRANSMITTING APPARATUS, B. Hoffmann, London.
24,077. FASTENINGS for DOOR KNOBS, F. H. Richards, London.
24,078. FLUID BRAKE MECHANISM, C. G. Emery, London.
24,079. CLEANING COFFEE, H. H. Lake.—(*D. B. Fraser, United States*.)
24,080. OIL PURIFIERS, D. H. McClelland and R. D. Jackson, London.
24 081. HEATING ATTACHMENTS for STOVES, J. Guy, London.
24,082. BOX for LANTERN SLIDES, T. Clement, London.
24 083. SWING BACK for PHOTOGRAPHIC CAMERAS, H. H. O'Farrell, London.
24 084. GAS ENGINES, V. Holliday, London.
24,085. WASH for CATTLE TRUCKS, C. T. Macadam, London.
24,086. HANDLES for MINERS' PICKS, T. H. Thacker, London.
24,087. ROASTING COFFEE BERRIES, N. H. Jensen, London.
24,088. VELOCIPEDES, P. H. J. Willis.—(*W. C. Foster, United States.*)
24,089. GAS ENGINES, G. C. Marks.—(*F. Hirsch, United States.*)
24,090. WHEELS for VELOCIPEDES, R. W. Thomas, London.
24,091. HANDLES BARS for BICYCLES, R. W. Thomas, London.
24,092. DISINTEGRATING THOMAS SLAG, E. Meyer, London.
24,093. BOOTS and SHOES, H. H. Lake.—(*Lincoln Sewing Machine Company, United States.*)
24,094. PORTABLE SEAT for SPORTSMEN, E. Keller, London.
24,095. COLOURING MATTERS, F. B. Aspinall, London.
24,096. MANUFACTURE of CARPETS, F. A. Bontor, London.
24,097. PUMPS for COMPRESSING FLUIDS, S. Puplett, London.
24,098. METALLIC STRUCTURES, G. E. Church and G. W. Ettenger, London.
24.099. ENVELOPES, W. M. Walker, London.
24.100. BOOTS, A. Wisotzky, London.
24,101. SEXTANT ATTACHMENTS, A. M. Clark.—(*T. T. H. Ferguson, China.*)
24.102. PREVENTION of SEA-SICKNESS, F. W. Kimball, London.
24,103. OXIDATION of FIXED OILS and FATS, S. Banner, Liverpool.
24,104 CARDING APPARATUS, W. P. Thompson.—(*Messrs. Seydel and Co.*, ——.)
24,105. NET TRAP, J. Morris, London.
24,106. CAGE TRAP, J. Morris, London.
24,107. PURSES, H. de Vere Pery, London.
24,108. GRIP for ROPE HAULAGE, S. Oliver and T. Ainsley, London.
24,109. DARK SLIDES for CAMERAS, M. A. Stubel, London.
24,110. CIRCULAR PETROLEUM BURNER, O. Wollenberg, London.
24,111. TUBULAR STEAM BOILERS, A. F. L. Reussner, London.
24,112. "SULKY" SPRING-TOOTH HARROWS, G. G. M. Hardingham.—(*The J. W. Mann Manufacturing Company, Canada.*)
24,113. MANUFACTURE of VINEGAR, J. Holt and J. G. Lorrain, London.

*12th December*, 1894.

24,114. REGULATING FEED-WATER, H. Bowman, T. S. McDonald, and G. F. Ross, London.
24 115. CASTORS, A. Bruce, Dundee.
24,116. TIRES, J. Almond, Manchester.
24,117. SEA-SHORE RESCUE APPARATUS, F. Wellington, London.
24,118. MECHANISM for PRODUCING MOTION, G. J. Stoney, London.
24,119 SAFETY APPARATUS for BESSEMER CONVERTERS, G. R. H. Bowden, Merthyr Tydvil.
24,120. CORD GUIDES for BLIND ROLLERS, J. Robertshaw, Manchester.
24,121. KNIFE-CLEANING MACHINES, J. A. Samuels, London.
24,122. WASTE-PREVENTING FUNNEL, J. A. McPherson, Bristol.
24,123. SOUND-PRODUCING APPARATUS, T. Mudd, West Hartlepool.
24,124. SPRINGS for CYCLE SADDLES, J. B. Brooks, Birmingham.
24,125. TOY, J. Quarton, Birmingham.
24,126. MANUFACTURE of BEDSTEADS, S. Wilson, Birmingham.
24,127. APPLIANCES for TABLE GAMES, R. Wallwork, Manchester.
24,128. WINDOWS, J. Barton, Glasgow.
24,129. DRIVING BELTS, W. Muir, Glasgow.
24,130. FASTENINGS for SLEEVE LINKS, F. Griffith, Birmingham.
24,131. VELOCIPEDES, W. F. Taylor and G. J. Philpott, Croydon.
24,132. RAILWAY FOG SIGNALLING APPARATUS, R. Reed, Lincoln.
24,133. GAS ENGINES, W. E. Heys.—(*L. Letombe, France.*)
24,134. BALL-POINTED HAIR-PINS, W. E. Heys.—(*C. Beaumont, France.*)
24,135. LAWN MOWERS, O. E. Zohe and H. A. Knapp, London.
24.136. REVERSIBLE SWITCH WALL SOCKET, W. J. Fryer, London.
24,137. FUEL ECONOMISERS, A. Lowcock, Manchester.
24,138. DUTCH OVENS, W. J. Porter, Birmingham.
24,139. UTILISING SLAG, J. Bromilow, Wellingborough.
24,140. APPARATUS for RAISING WRECKS, G. A. Russell, Newport.
24,141. LOOM SHUTTLES, J. Waddington, Bradford.
24,142. STARTING, &c., MACHINERY, J. H. Scott, Glasgow.
24,143. SPINNING TOPS, S. Erhard, Halifax.
24,144 VENTILATING BOOTS and SHOES, H. J. Pond, Norwich.
24,145. CONSTRUCTION of HAIR-PINS, C. Beaumont, Manchester.
24,146. HIGH-PRESSURE SAFETY BALL-VALVE, S. Shears, Exeter.
24,147. FIRE-DOORS for BOILER FURNACES, G. H. Pilling, Manchester.
24 148. COOKING RANGES, L. H. Teale and R. M. Somers, Leeds.
24,149. BRUSH and BLACKING BOX, J. Hunter, Renfrewshire.
24,150. APPLIANCES for FEEDING BOILERS, A. W. Binning, Glasgow.
24,151. REST for BILLIARDS, G. R. Short, Merthyr Tydvil.
24,152. DRIVING GEAR for BICYCLES, J. J. Raggett, Birmingham.
24,153. LIQUID STRAINERS, P. Watson, Keighley.
24,154. LAVATORIES, J. T. Twist, Glasgow.
24,155. REEL or WINCH for TOWING LINES, W. H. A. Theed, Penzance.
24,156. MAKING LEATHER, R. Pope and A. Cleaves, Bristol.
24,157. SHIRT FRONT STIFFENER, W. E. and B. A. Manning, London.
24,158. DRIVING ACTION, J. Turnbull, Plumstead, Kent.
24,159. BOOT HEELS, M. Schweiger and N. Becker, Halifax.
24,160. SIZING and SLASHING MACHINES, T. Crook, London.
24,161. SUPPORTS for SIGNAL, &c., RODS, A. G. Evans, London.
24,162. GEARING for DRIVING CYCLES, A. van Noorden, London.
24,163. TUBULAR FRAMES for CYCLES, R. S. Lovelace, London.
24,164. SEWING MACHINES, W. P. Thompson.—(*C. Clausen, Germany.*)
24,165. MEANS for SECURING DOORS, A. B. Buckland, London.
24,166. PENS and PENCILS, E. Whitworth, London.
24,167. PREVENTING JOURNALS HEATING, G. A. Mower, London.
24,168. BOAT RELEASING APPARATUS, J. C. Robinson, London.
24,169. STACK and ROOT-LUMP PROTECTORS, L. H. de V. Shaw, London.
24 170. SELF-REGISTERING THERMOMETERS, S. Richardson, London.
24 171. WEATHER CHECKS, W. Youlten, London.
24,172. SPINNING BOBBINS, L. Oliven, London.
24.173. ELECTRIC MOTORS, H. H. Lake.—(*H. Guttman, Germany.*)
24,174. FEEDING PRINTING MACHINES, H. C. Watson, London.
24,175. PAPER-FOLDING MACHINES, H. C. Watson, London.
24,176. SHIRTS, A. E King, London.
24.177. STARTING TRAMCARS, &c., E. Chadwick, Liverpool.
24,178. CLEANING SURFACES, J. Waterhouse and W. G. Naylor, Liverpool.
24,179. RECORDING PIECES of MUSIC, A. Simon, London.
24,180. WASHING-MACHINES, A. Panne, London.
24,181. BRACELET-FASTENING DEVICE, G. Dattlebaum, London.
24,182. POLISHING SHEET METAL, Ingall, Parsons, Clive, and Co., Ld, and W. H. Elkington, London.
24,183. BUTTONS, T. Cook and J. H. Ingle, London.
24,184. NECKTIE-FASTENERS, J. H. Hines, jun, London.
24,185. DRIVING-GEAR for CYCLES, H. P. Villevé, London.
24,186. SHIRTS, J. Hatfield, London.
24,187. SECURING HOLLOW RINGS in POSITION, B. Willcox.—(*The firm of C. Zeiss, Germany.*)
24,188. REAPING, &c., MACHINES, A. and J. Shanks, London.
24,189. STOP-VALVES, E. Edwards.—(*A. Anders, Germany.*)
24,190. ADJUSTABLE SPANNERS, E. Edwards.—(*O. Schach, Germany.*)
24 191. DAMPING PRESS-COPYING LETTERS, J. R. Greenhalgh, London.
24,192. PROTECTING TYPE-WRITERS from DUST, J. R. Greenhalgh, London.
24,193. DRYING GARDEN TURF, J. O. McQuone and W. J. Baker, Scarborough.
24,194. MULTIPLE FUSE BOX, E. A. Parson and H Millar, Philadelphia.
24,195. CONTROLLING MAGNETIC ENERGY, H. M. Paine and A. R. Brandley, Philadelphia.
24,196. DRILLING MACHINES, W. W. Hulse, London.
24,197. SYSTEM of SIGNALLING on RAILWAYS, E. Prew, London.
24,198. ELECTRICAL RESISTANCES, A. J. Marquand, E. Hancock, and D. Lowdon, London.
24,199. COMPOSITIONS for COATING BOILERS, J. A. Fisher, London.
24,200. WASHING MACHINES, C. E. Halls, London.
24,201. CUFFS, G. H. Halley, London.
24,202. PENHOLDERS, H J. Griffith, London.
24,203 DETACHABLE PIPE COVERS, S. H. Crocker, London.
24,204. MOWING MACHINES, W. G. Sidley, London.
24,205. PASTRY BOARD, H. J. Griffith, London.
24,206. INKSTAND, A. Howell, London.
24,207. TOBACCO PIPES, F. D. Jones, London.

*13th December*, 1894.

24,208. INDICATOR for GAUGES, T. Gibson, R. H. Ealey, and J. Thorpe, Huddersfield.
24,209. COUNTING ATTACHMENT, S. A. N. Deluce, Manchester.
24,210. BALLING INSTRUMENT for HORSES, H. Sewell, Northamptonshire.
24,211. RAILWAY PERMANENT WAY, A. J. Hamilton-Smythe, London.
24,212. METHOD of SIGNALLING, G. Blakeley, Bournemouth.
24,213. LADIES' PURSES, H. A. Wanklyn, London.
24,214. CARDBOARD BOXES, H. A. Wanklyn, London.
24,215. CYCLISTS' TROUSER RETAINER, R. S. Boyer, London.
24.216. COMPOSING STICKS, R. W. Barker.—(*N. S Perkins, United States.*)
24,217. SPINNING FRAME TRAVELLERS, H. Whittaker, Halifax.
24,218. CASH CARRIERS, The Henderson Store Railway, Ld.—(*The Barr Cash and Package Carrier Company, United States.*)
24,219. RAILWAY SIGNALLING APPLIANCES, E. Williamson, Nottingham.
24,220 STUD and SOLITAIRE FASTENINGS, T. Wall, Birmingham.
24,221. METALLIC GLAND PACKING RINGS, C. Geddes, Hartlepool.
24,222. ADDITIONS to WAIST BELTS, &c., P. A. Martin, Birmingham.
24,223 SPINNING and DOUBLING COTTON, H. Stuttard, Oldham.
24,224. VALVE GEAR for MOTIVE-POWER ENGINES, W. Walker, Erith, Kent.
24,225. DRESS HOLDERS or SUSPENDERS, E. A. Rickett, Liverpool.
24,226. LOCKING DEVICES for CYCLES, T. E. Weaver, Wolverhampton.
24.227. FASTENINGS of UMBRELLAS, W. Holland, jun., Birmingham.
24,228. GOLF BALLS, J. H. Exley, Bradford.
24,229. PORTABLE INCANDESCENT GAS LIGHT APPARATUS for PHOTOS, P. H. D. Buttrum and W. Thorneycroft, Newport Pagnell, Bucks.
24,230. GULLY TRAPS and GRATINGS, R. Taylor and J. S. Green, Manchester.
24,231. COIN PREPAYMENT METERS, D. B. Peebles, Glasgow.
24 232. CLEARING HOOK for ANGLERS, H. Warry, Totnes.
24,233. GRINDING and CRUSHING MILLS, P. A. Cook, Liverpool.
24 234. REFLECTORS, P. Körber, Glasgow.
24,235. AMMUNITION, A. F. Hargreaves, Midlothian.
24,236. PENDANTS, W. Beal, Birmingham.
24,237. STRETCHING, G. F. Butterworth, Manchester.
24,238. SEWING MACHINE NEEDLES, L. H. Smith, Glasgow.
24,239. GAS ENGINE, S. Withers, London.
24,240. APPARATUS for FLYING, W. Smith, Aberdeen.
24,241. CYCLE SADDLES, R. E. Phillips, London.
24,242. AFFIXING STAMPS, A. Welsh and W. Muir, Glasgow.
24,243. CHAIRS, G. Taggart, Glasgow.
24,244. STOCKINGS, W. Munro, Glasgow.
24,245. PREVENTING SHUTTLES FLYING OUT, W. Aitken and J. Angus, Galashiels.
24,246. CHANGE GIVER, W. Busse, London.
24,247. UMBRELLA FASTENER, E. C. Lea and D. Parker, London.
24,248. CHEEK PLUMPER, E. Bowland, London.
24,249. PACKAGE for TRANSPORTING LIQUIDS, H. B. Care, London.
24,250. WHEELS for VEHICLES, T. S. Truss, London.
24,251. CULTIVATOR TEETH, L. M. Jones and W. F. Johnston, London.
24,252. STARTING TRAMCARS, J. C. Fisher, London.
24,253. TOBACCO PIPES, W. R. Yates, London.
24 254. TORPEDOES, E. O'Neill, London.
24,255. GAME, H. T. Berry, London.
24,256. GASHOLDER, W. H. Westwood, E. T. Wright and W. W. S. Westwood, London.
24,257. LIFEBOAT, J. H. Raffety, West Worthing.
24,258. BUCKLE, W. Pritchard and T. E. Williams, London.
24 259. CYCLE WHEELS, M. Kohl and L. Serwotka, London.
24,260. SWING, C. Zeisberg, London.
24,261. CYCLE CRANK, J. Boyd, Dublin.
24.262. SURGICAL INSTRUMENTS, J. E. Arnold, London.
24,263. HORSESHOE, J. L. Ley, A. C. McIver, and G. M. Gordon, London.
24,264. PLATEN PRESSES, G. Eastwood, London.
24,265. GAS STOVES, W. Dresser, London.
24,266. ELECTRO-MOTORS, A. Bergtheil and R. A. Marples, London.
24,267. BOILERS, Simpson, Strickland, and Co, and F. Strickland, London.
24 268 EYEGLASSES, T. Smith, London.
24,269. LIFTING TACKLES, A J. Boult.—(*C. Foccroulle, Belgium.*)
24,270. EMBOSSING STAMPS, W. R. Mudd, London.
24,271. BOTTLE, W. V. Bokern and H. Heatley, London.
24,272. LETTER HOLDER, R. K. Birkbeck, London.
24,273. SUPPORTS, J. D. Reed, London.
24,274. COLLECTING DUNG, E. M. Milborne Swinnerton-Pilkington, London.
24,275. SELF-ACTING MULES, G. Josephy, London.
24,276. ROPES, B. Kirsch and A. Pessl, London.
24,277. WARP BEAM TENSION APPARATUS, J. Taylor London.
24,278. METALS, C. D. Abel.—(*Electricitäts Gesellschaft Gelnhausen mit beschrankter Haftung, Germany.*)
24,279. TIRES, W. Mackintosh, London.
24,280. BICYCLES, E. Jonckheer, London.
24,281. SHIPS' DAVITS, S. O. Cowper-Coles, London.
24,282. GLASS GAUGES, H. H. Lake.—(*The Penberthy Injector Company, United States.*)
24,283. STEAM PLOUGHS, R. Pearson, London.
24 284 PREVENTING WITHDRAWAL of CORKS, J. Eskdale, London.
24,285. ELECTIC LIGHTING, A. G. New and A. J. Mayne, London.
24,286. COAT HANGER, W. J. Cowley, London.
24,287. SMOKELESS FURNACE, C. A Jensen.—(*R. Müller, Norway.*)
24,288. CARDING, E. Gessner, London.
24,289. GUNS, H. H. Lake.—(*J. B. G. A. Canet, France.*)
24,290. SPANNERS, H. Salsbury, London.
24,291. SECURING TERMINAL WIRES, F. A. and N. von Alimonda, London.

*14th December*, 1894.

24,292. COOKING RANGE, J. A. Pearce, Tavistock.
24,293. DETERMINING HEAT, W. E. Ayrton and H. C. Haycraft, London.
24,294. PROPELLER SHAFTS, W. B. Thompson, Dundee.
24,295. FLANGING FURNACES, W. Deighton, Leeds.
24,296. SIGNALS, V. L. Baven and C. Baister, Stockton-on-Tees.
24,297. POROUS CELL, W. McChleary, Glasgow.
24,298. FILLING PASTE, J. McMaster, Liverpool.
24.299. INFLATOR CLIPS, H. Hill, Sheffield.
24,300 MOP, C. T. and M. D Hale, Birmingham.
24,301. TALLY MARKER, R. D. O'Brien, Birmingham.
24,302. TURN-TILE, W. T. Ellison, Manchester.
24,303. GAS FITTINGS, J. and J. Parkes, Birmingham.
24,304. SLIDING SASHES, J. Donnelly, Longport.
24,305. COMBS, A. N. Sharp, and S. Metcalfe, Bingley.
24,306. LIQUID-SPREADING MACHINES, E. Wilkinson, Norwich.
24,307. FLANGE WATER-PIPE COUPLINGS, J. Graham, Workington.
24,308. GERM EXTRACT, T. Chamings, Exeter.
24,309. LOOM PICKING APPARATUS, B. Ross, E. Moorhouse, and M. O'Neill, Bradford.
24.310. PRODUCING ANTISEPTICS by OZONE, E. Andreoli, London.
24,311. GRINDING CARD FILLETING, J. S. and J. Dronsfield, Manchester.
24.312. LACE HOLDER for BOOTS, E. F. Haynes and T. S. Griesbach, Birmingham.
24.313. ALUMINATES of ALKALIES, A. G. von Grätz, London.
24,314. BLOCKS and GINS, T. V. Moody, Mill-on-Tyne.
24,315. BLACK LEAD SHARPENER, E. T. John and A. Charles, Cardiff.
24,316. LOCOMOTIVE ENGINES, J. W. Willans, Leeds.
24,317. BOTTLES, P. S. Brown and H. J. S. Brown, Glasgow.
24,318. STEAM ENGINES, J. R. Bird, Glasgow.
24,319. WHEELS for CYCLES, &c, J. L. Corbett, Glasgow.
24 320. FEED-WATER HEATERS, C. A. Knight and G. W. Thode, Glasgow.
24,321. MOTORS, H. D. Fitzpatrick, R. McL. McDonald, and A. Nimmo, Glasgow.
24,322. CURING SORES, &c., on ANIMALS, J. Smith, Glasgow.
24,323. GAS GENERATORS for FURNACES, W. Muirhead, Glasgow.
24,324. REGULATING WATER in PIPES, J. Tweeddale, Paisley.
24,325. TERICYCLE, R. Milligan, Hawick.
24,326. MEASURING and MARKING TUCKS, E. Grimes, Norfolk.
24,327. NECKTIES, W. Ruttenau and C. Hahlo, Manchester.
24,328. PIANOFORTE PEDAL ATTACHMENT, T. Smith, Liverpool.
24,329. A SANITARY DOMESTIC FILTER, F. Thomas, London.
24,330. PREVENTING CYCLES SLIPPING, W. A. Medland and W. C. Shillito, Twickenham.
24,331. A NEW CAP, E. Iredale and W. H. Iredale, London.
24,332. DRIVING GEAR for CYCLES, &c., E. A. Seyd, London.
24,333. RAZOR STROPS, S. D. Lacey, London.
24,334. CHALK HOLDER for BILLIARDS, A. Stewart, London.
24,335. VELOCIPEDES, S. J. Kent, London.
24,336. VELOCIPEDES, S. J. Kent, London.
24,337. FASTENING BOOTS and SHOES, F. J. Tregoning, London.
24,338. TEATS, F. T. Fletcher, London.
24,339. CHIMNEY POTS, F. T. Myerson and T. Lane, London.
24,340. ELECTRICAL NAIL DETECTOR, F. Jones, London.
24,341. TRANSMITTING POWER from PRIME MOVERS, A. B. Greig, London.
24,342. CONDENSING PHOTOGRAPHIC LENSES, J. Harrington, London.
24.343. SUPPORT for RAILWAY TRAVELLERS, C. Larue, London.
24.344 DECORTICATING FIBROUS PLANTS, J. C. Walker, London.
24,345. MOTORS, A. Gardon and A. Butavent, London.
24 346. DRAUGHT EXCLUDERS, E. J. Sherman, London.

24,347. Manufacturing Cycle Wheels, M. Pedersen, London.
24,348. Manufacturing Boots and Shoes, C. Lewis, London.
24,349. Pianofortes, J. L. Courtice and J. Wood, London.
24,350 Steam Traps, J. H. Brinjes London.
24,351. Manufacture of Cigarettes, W. S. Holding, London.
24 352. Fixing Tubes in the Barrels of Fire-arms, H Ehrhardt, London.
24 353. Brackets for Poles, Siemens Bros. and Co , Ld., and G. W. Perry, London.
24,354. Saucepan Handles, C. F. Clark, J. Sanders, and J. Webster, London.
24,355 Cords for Blinds and the like, A. B. Dashwood, London.
24,356. Tobacco Pipes, G. Sant London.
24 357. Paper Weight, A. Pritchard, London.
24 358 Machines for Mincing, &c., W. F. Anderson, London.
24,359. Driving Gear for Velocipedes, A. F. Bowers, London.
24.360. Coating Iron with Nickel, The Cowper-Coles Galvanising Syndicate, Ld., and S. O. Cowper-Coles, London.
24,361. Transposing Music, G. E. Prince, London.
24,362. Construction of Ships, &c., A. M. Wood, Surrey.
24 363. Bicycle, A. Lambert, London.
24,364. Treating Battery Slimes, P. De Wilde, London.
24,365. Composition for Use with Fertilising Substances, A. L. Radford and M. F. Hutton, London.
24,366. Mouthpiece for Musical Instruments, W. P. Thompson.—(*C. G Schuster, Germany* )
24,367. Mangles, I. Braithwaite and E J. Stanley.—(*Messrs. A. T. Hagen and Co., United States* )
24,368. Joining the Ends of Machine Belting, W. Davidson and T. Denholm, Liverpool.
24,369. Electric Bells or Alarms, J. T. Brierley, Liverpool.
24 370. Bags for Keeping Bottles Hot, S. G. Edmonds, Liverpool.
24,371. Driving Belts for Machinery, T. C. Dennison, London.
24,372. Shade Holders for Gas, S. Sinauer.—(*The Utility Shade Company, United States* )
24,373. Propelling Screw Steamers, M. Sandison, London.
24,374. Insulation of Electric Wires, F. Clouth, London.
24,375. Tandem and other Bicycles, E. C. Hill, London.
24,376. Brake for Wheels of Cycles, S. Hilton, London.
24,377. Direct-acting Pumping Engine, J. Patterson, London.
24,378. Doll, F. G. Lloyd.—(*W. Bevan, New Zealand.*)
24,379. Drying Coffee and other Grain, A. F. Ramos, London.
24,380. Repairing Damaged Natural Teeth, M. Salier, London.
24,381. Curing Tobacco, H. Neill.—(*H. A. Wickham, Australia.*)
24,382. Flushing Tanks, L. Janlet, London.
24,383. Flushing Tanks, L. Janlet, London.
24,384. Sieve, W. P. Thompson.—(*E. Picard, Belgium.*)

*15th December*, 1894.

24,385. Electric Supply Meters, J. Perry, London.
24 386. Driving Gear, W. J. Hamilton and W. Leatham, Belfast.
24,387. Card or Pattern Cylinder, P. H. Hartley, Lancashire.
24,388. Bi-autographic Check Tills, E. M. Sellors, Dublin.
24,389. Hat and Umbrella Holder, G. H. McKay, Glasgow.
24,390. Spoons, P. McInnes, Glasgow.
24,391. Poker, J. V. Moore and T. E. Dunnett, London.
24,392. Castor Pegs for Bedsteads, S. Wilson, Birmingham.
24,393. Card Stampers, J. Cash, S. Cash, and T. Cash, London.
24,394. Fluid Pressure Motors, J. Mackintosh, Dundee.
24,395. Manufacturing Block Tin Piping, A. Barraclough, Yorks.
24,396. Safety Appliances for Lifts, C. and A. Musker, Liverpool.
24,397. Boxes for Holding Twine, &c., G. C. Paton, Glasgow.
24,398. Manufacturing Traverse Net Lace, R. Scott, Nottingham.
24,399. Lubricators, W. Greenhalgh, Leeds.
24,400. Machine for Bundling Firewood, E. Needham, Shepton Mallet.
24,401. Clip for Marking Music, &c., G. H. Davies, London.
24,402. Portrait or Picture Frames, R. Hall, Manchester.
24,403. Curtain Poles and Brackets, T. Little, Manchester.
24,404. Separating Hair from Hides, J. Marshall, Manchester.
24,405. Ink Eraser, E. T. John and C. W. Chabrel, Cardiff.
24,406. Ventilating Cyclists' Clothing, J. B. Smith, Birmingham.
24,407. Urinals, F. A. Wells, Manchester.
24,408. Forming Box Pleats, H. M. Speakman and W. E. Kerslake, Liverpool.
24,409. Axle-box for Cycles, E. Hettich, Berlin.
24.410. Cigarette Cases, J. and J. Wertheimer, Manchester.
24,411 Manufacturing Raw Spirit, K. von Radziszewski, Berlin.
24,412. Couplings for Railway Wagons, A. Cameron, Glasgow.
24,413. Lubricators, G. B. Goodfellow and E. A. Pickup, Manchester.
24,414. Pumping Apparatus, J. Gwynne, London.
24.415 Slides of Presses, J. W. Hunt and The Chillington Tool Company, Ld., Wolverhampton.
24,416. Handle-bars of Bicycles, W. H. Boyington, London.
24,417. Keyboards for Pianofortes, J. Clarkson and F. W. Merridew, Manchester.
24,418. Draw-off Cock and Safety-valve, A. Marriage, London.
24,419. Puzzle, E. G. Stevens, London.
24,420. Fastening Hats and Bonnets, R. H. Courtenay, London.
24,421. Adjustment of Lamp Chimneys, R. Campe, London.
24,422. Grip for Carrying Parcels, F. Mann and H. H. Akers, London.
24,423. Railway Signalling Devices, A W. Ellis and S. A Payne, London.
24,424. Railway Signalling Apparatus, C. M. Hope, London.
24,425. Lamps for Cycles, F. E Wilkins, London.
24 426. Feeding-troughs for Pigstyes, G. Brain, jun , London.
24,427. Combination Tool, J. Boorer, London.
24,428. Stoves or Fireplaces, A. R. Smith, London.
24,429. Binding of Sheets and Cards, E. B. Smith, Harrow-on-the-Hill.
24,430. Pumping Well Bores, W. Mather, London.
24 431. Posts, Siemens Bros. and Co. and G. W. Perry, London.
24,432. Driving Gear of Bicycles, R. Blackburn and A. B. Spring, London.
24,433. Boxes for Tooth Brushes, T. Bellis, London.
24,434. Toasting Forks, H. E. Aspinall and W. Barwell, London.
24,435. Door-closer and Lubricator, H. Kühn, London.
24,436. Sash Fastener, J. Eastham, London.
24.437. Pails, W. H. Brookes and Moodys and Kelly, London.
24,438. Lamp Globes and Lamp Glasses, C. Jousset, London.
24.439. Moving Wheeled Carriages, J. W. Couchman, London.
24 440. Connecting Telegraph Wires, W. B. Shaw, Liverpool.
24,441. Preventing Electrical Sparks, W. Ostwald, London.
24,442. Gelatine Sheets, F. Blenkins and F. G. Bate, London.
24,443. Cleansing Tires, J. Argylle and A. Argylle, London.
24,444. Sweater, P. O'Neil. London.
24,445. Pneumatic Tires for Wheels, P. A. Craven, London.
24,446. Manufacture of Perfumes, M. Otto and A. Verley, London.
24,447. Distilling, M. Otto. London.
24,448. Hair-pin, T. A. Nixon and C. V. Craster, London.
24,449. Connecting Belts, J. Gothard and L. A. Parrock, Birmingham.
24,450. Watches, W. Cross, London.
24 451. Indicating Distances Travelled, W. Vernum, London.
24,452. Grain Binders, W. C. Barker, London.
24,453. Disintegrators, J. H. Carter, London.
24,454. Apparatus for Dyeing Hair, A. Gasthuys, London.
24,455. Cigarettes and Cigars, J. Horwitz, London.
24,456. Securing Flanges to Pipes, C. Wellin.—(*C. Vassel, France* )
24,457. Evaporating Liquors, &c , E. G. Scott, London.
24,458. Announcing the Departure of Trains, H. Stockheim and O. Strohbach, London.
24,459. Tobacco Pipes, C. Weissenborn and W. Feige, London.
24,460. Elastic Springs for Dobby Machines, R. H. Attwater, London.
24,461. Making Armour Plates, S. O. Cowper-Coles, London.

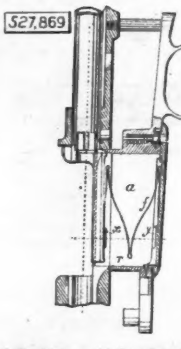
## SELECTED AMERICAN PATENTS.

*From the United States Patent Office Official Gazette.*

**527,869.** Magazine for Breech-loading Fire-arms, *P. Mauser, Oberndorf, Germany.—Filed September 15th*, 1893.

*Claim.*—(1) In a breech-loading bolt gun, the receiver, the magazine, and bolt, in combination with a trigger-guard consisting of a single integral piece of metal having the fixed cartridge magazine *a* in its forward part said guard having upright walls surrounding said magazine and seating at top against the under side of said receiver, said guard having grooves *s* at bottom, and the bottom plate for said magazine removably connected thereto, and having lugs *r* entering said grooves and retaining said plate in position on said magazine, and a snap catch carried by said guard and engaging said plate for preventing separation of the latter. (2) In a breech-loading bolt gun, the receiver and bolt, in combination with a magazine *a* and a carrier plate *b* thereon having a rib $b^1$ on its upper face, and projections *x* on its under face, of a trigger guard having said magazine formed in its forward part, a bottom plate *c* closing said magazine, and having projections *y*, and a leaf spring *f* in said magazine connected to said bottom plate by said projections *y* and to said carrier plate by said projections *x*, substantially as set forth.

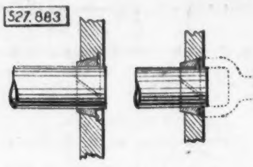
527,869



**527,883.** Tube Joint for Sectional Boilers, *N. W. Pratt. Brooklyn, N.Y.—Filed March 28th*, 1891.

*Claim.*—(1) A means of securing a tube in its seat, a divided ring or collar of ductile material having its inner bearing surface conformed to the tube and its outer surface to a tapered seat in the sheet, plate, or header to which the tube is secured. (2) The herein described tube connection, consisting of a tube seat therefor of tapered form and having an annular groove therein, and a soft metal annulus adapted to the tube and its seat and having a projection for caulking the annulus in place and adapted to interlock with said annular groove.

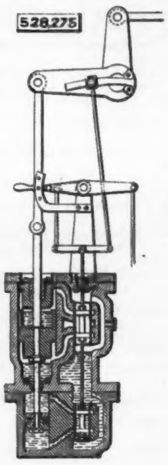
527.883



**528,275.** Engine Reversing Gear, *C. E. R. Martin, Philadelphia, Pa.—Filed March 29th*, 1894.

*Claim.*—(1) The combination of the cylinders and pistons, of the link controlling lever connected to said pistons, valves for said cylinders, a valve stem, two pivoted levers, one connected to said valve stem, and the other to a speed governing mechanism, and means for locking said levers together, substantially as described. (2) The combination of the cylinders, pistons therein, a piston-rod extending from said pistons and connected to the link controlling lever of the engine, the valves, a valve stem, a floating lever centrally connected to said valve stem, a reversing lever connected to one end of said floating lever, and the opposite end thereof being operatively connected to the link controlling lever, an automatic speed-governing mechanism and a lever operatively connected thereto and adapted to be locked to the reversing lever, substantially as described.

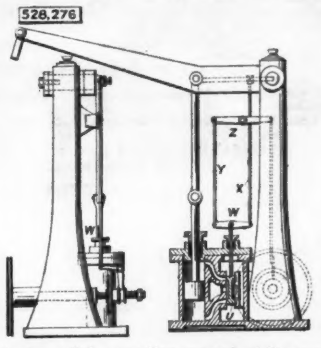
528,275



**528,276.** Engine Governor, *C. E. R. Martin, Philadelphia, Pa.—Filed February* 1st, 1893.

*Claim.*—(1) In a steam engine governor, the combination of a threaded spindle driven by the engine, a sleeve loosely mounted on the said spindle and driven by an independent motor, a piston connected with the reversing gear of the engine, a valve controlling said piston, connections between said valve and the loose sleeve, and connections between said valve and the reversing gear of the engine. (2) The combination of a piston connected with the reversing lever of the engine. a valve controlling said piston, a vibratory crosshead pivoted to the upper end of the stem of said valve, a link connecting one end of the crosshead with the engine reversing lever, and mechanism connected with the opposite end of said crosshead to actuate the same upon a variance in the speed of the engine. (3) The combination of the threaded spindle driven by the engine, the sleeve mounted thereon and driven by an independent motor, the levers N and *b*, the links X, Y, and M, connecting-rod *a*, arm Z, crosshead W, valve U, and piston L, all arranged and operating substantially as specified.

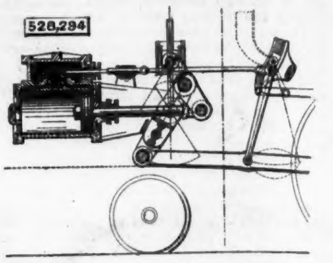
528,276



**528,294.** Means for Counterbalancing Momentum of Reciprocating Elements, *M. N. Forney, New York N Y.—Filed February 13th*, 1894.

*Claim.*—(1) The combination, with a reciprocating piston and piston-rod, of a primary lever connected at one end to the piston-rod and at the other to a sliding member, a fixed guide on which the sliding member moves rectilinearly, a secondary lever journalled in fixed bearings and having one of its arms pivotally connected to the primary lever at the middle thereof, and a connecting rod connected to the opposite arm of the secondary lever, and to a crank, substantially as set forth. (2) The combination of a cylinder, a piston secured to a piston-rod and reciprocating in said cylinder, a distribution valve working on a valve face above the lower line of said cylinder, a counterbalancing lever system, substantially as set forth, coupled to the piston-rod, a connecting rod coupled to said counterbalancing lever system and to a crank pin, a link oscillating in fixed bearings, a block fitted to slide therein, a lever coupled to said block and to the connecting rod, and connections coupling said link with a distribution valve, substantially as set forth.

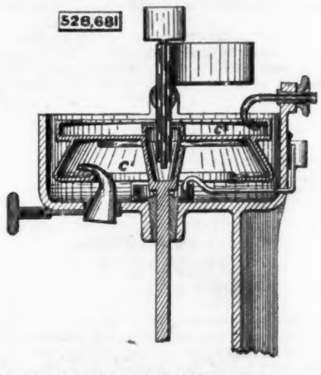
528,294



**528,681.** Churn, *O. Ohlsson, Newark, N.J.—Filed September 16th*, 1890.

*Claim* —(1) In a centrifugal churn, the combination, with an outer stationary casing, of a cream chamber, a shaft upon which said cream chamber is mounted, chambers C′ and C² carried by and connecting with said cream chamber, a pipe having transverse bars on the inside thereof and connecting with said cream chamber and the chamber C′, a conduit connecting said chambers C′ and C² and means for collecting and delivering the butter and the butter-milk into vessels arranged to receive the same as described for the purposes set forth. (2) In a centrifugal churn, the combination of a cream receptacle, upper and lower chambers communicating with each other, a pipe or conduit leading from the cream receptacle to the lower chamber, said pipe having devices for churning the cream, and mechanism for revolving the said receptacle, chambers and pipe, for the purpose described.

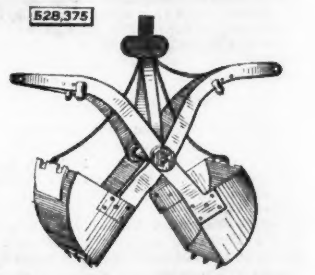
528,681



**528,375.** Dredging Implement, *C. Meier, San Francisco, Cal.—Filed October 19th*, 1893.

*Claim.*—(1) In a dredging machine of the class herein-described, the combination, with the hinged scoops, of the fixed bottom plate on the leading edge of each scoop, the removable top plate on the inner side of the scoop over the fixed bottom plate, the edge whereof is bevelled in the opposite direction to the corresponding edge of the said bottom plate, and the wedge shape teeth or projections secured under the bottom plate and extending forward beyond the cutting edge formed by the bevelled plates, the said teeth being recessed for the bottom plate and having a curved bottom face tapering from the heel upward to the point, substantially as hereinbefore set forth. (4) The combination, with the scoop or bucket. of the removable plate having a bevelled cutting edge and the bottom plate having a cutting edge bevelled oppositely to the edge on the upper plate, substantially as hereinbefore set forth.

528,375



Epps's Cocoa.—Grateful and Comforting.—"By a thorough knowledge of the natural laws which govern the operations of digestion and nutrition, and by a careful application of the fine properties of well-selected Cocoa, Mr. Epps has provided for our breakfast and supper a delicately flavoured beverage which may save us many heavy doctors bills."—*Civil Service Gazette.*—Made simply with boiling water or milk. Sold only in packets, by Grocers, labelled, "James Epps and Co, Homœopathic Chemists, London."

END OF VOL. LXXVIII.
